The results of this aluminum gel and dietary regimen are given in table 5. For the critical evaluation of the results of this method of therapy, it seemed best to tabulate the data in terms of the number of kidneys which had previously been, or were still, the site of calculi. In the 22 patients under study there were 36 kidneys which fulfilled these requirements. Prior to the institution of therapy, five patients had had a nephrectomy for nephrolithiasis, and in three there was a history of calculus formation confined to one kidney. The three uninvolved kidneys in this latter group were excluded from consideration in the tables, inasmuch as it was not possible to decide whether their continued freedom from calculi during therapy might have existed in its absence. Some overlap is evident in table 5, because in some cases changes were observed in different directions in each kidney with respect to the stones in situ. Thus, of the kidneys listed under group *A,* two were in patients with stones in situ in the opposite kidney; hence, these patients are also listed in group *B.*

Staph albus or Staph. aureus, Streptococcus or sterile	10	1
Total	22	

Of the six kidneys (five patients) from which stones had been removed and from which they were still absent when therapy was instituted, in no instance did stones recur. Of 30 kidneys (19 patients) with stones in situ, the stones disappeared completely from four (two patients), decreased in three (three patients) and exhibited no change in 20 (13 patients). These favorable results comprise 90 per cent of the group of kidneys with stones in situ at the institution of therapy. In three kidneys (three patients) the calculi increased approximately 1 cm. in greatest diameter during therapy, without further increase in size during the succeeding year. There were no associated changes of adverse clinical significance, in terms of either symptoms or renal function. It is of interest that one of the patients was pregnant when therapy was instituted and was receiving additional calcium as calcium lactate. She received continuous aluminum gel therapy; the stones present in both kidneys were passed spontaneously, and

she was delivered of a full term healthy infant. In at least four patients not included in this series because of their voluntary or inadvertent discontinuation of therapy, within a year there was a decided increase in the size of the calculi of such magnitude as to require operative removal.

---

[10] Dr Victor F Marshall and his staff of the Department of Urology of the New York Hospital evaluated the roentgenologic changes in these patients during therapy

It was of interest to correlate the changes in the size of the calculi with the average 24-hour urinary excretion of phosphorus during aluminum gel therapy. The urinary phosphorus excretion of a patient on the average American diet is approximately 1 Gm. per 24 hours. Eighty per cent of the patients excreted less than 500 mg. per 24 hours (table 6). In this group were included three kidneys (three patients) in which there was a small increase in the size of the stones. There was no change in size of the calculi in three kidneys (two patients) whose urinary phosphorus excretion per 24 hours ranged from 600 to 800 mg. It is perhaps of relevance that both of these patients were free of urinary tract infection.

Since on the institution of treatment the diet and aluminum gel dosage of each patient were adjusted to achieve a urinary phosphorus excretion of approximately 300 mg. per 24 hours, the variations from this level over the subsequent years of therapy indicate the extent to which deviations from the prescribed diet or medication are likely to occur in an ambulatory group of patients. That these variations were not attributable to any diminished effectiveness of aluminum gels was evident from repeated studies on individual patients under controlled conditions in the Metabolism Ward. Occurrence of these variations emphasizes the necessity for frequent 24-hour urinary phosphorus analyses for the proper regulation of this therapeutic regimen.

Table 6.—*Relationship of Recurrence or Change in Calculi Size to Average Urinary Phosphorus Excretion*

Average Urinary Excretion			No. of Kidneys			
Phosphorus Mg./24 Hr.	Calcium Mg./24 Hr.	No. of Infected Urines	No Recurrence	Decrease in Size	No Change in Size	Increase in Size
100 to 200	166	3	1	3	4	..

500 to 600	...	..	..	..	..	..
600 to 700	243	0	..	..	1	..
700 to 800	275	0	..	..	2	..

Data are given on 2 cases to provide more detailed information on the history and laboratory observations prior to and during aluminum gel therapy. Patient J. C. (case 2) had the uniformly low urinary phosphorus excretion which can be obtained with prolonged aluminum gel therapy by a patient who is scrupulous in his adherence to the prescribed regimen. His stormy calculous history prior to aluminum gel therapy would seem to justify one's attributing his subsequent freedom from stones to the effects of this regimen. In patient M. T. (case 1) treatment was complicated by impaired renal function and severe infection of the urinary tract with ammonia-forming organisms, with the urinary p_H at levels of 8.0 to 8.5. After two years of therapy a staghorn calculus was removed from one kidney. Despite persistent infection on that side and an alkaline urine highly favorable to phosphatic stone formation, that kidney has remained stone free for four years since operation, during which time the patient has been receiving continuous aluminum gel therapy. Repeated ureteral catheterizations demonstrated that this kidney was secreting urine throughout the period of observation.

REPORT OF CASES

Case 1.—*History.*—M. T., a man aged 59, in December 1937 had left flank pain with chills and fever. In April 1938 he had left flank pain and pyuria. In July 1938, he had left and right flank pain; roentgenograms showed bilateral renal calculi, and he passed several calcium phosphate calculi. In March 1939 he had right renal colic with the passage of a calculus. In April 1939 he had right flank pain and passed a right ureteral calculus. In February 1940, during right flank pain, roentgenograms revealed a tremendous increase in calculi and no renal function on the right; he had a right ureterolithotomy and a left pyelolithotomy. In May 1940 he had a right pyelolithotomy; at this time roentgenograms showed small bilateral calculi with good excretory function. Follow-up roentgenograms displayed calculi increasing in size, with no excretory function on the left and slight function on the right.

Laboratory Results.—The serum calcium level was 10.40 mg. and serum phosphorus 3.31 mg., per 100 cc. The alkaline phosphatase level was 3.8 Bodansky units. The total protein was 7.35 Gm. and the blood urea nitrogen 18 mg., per 100 cc. Urine cultures showed A. aerogenes and B. pyocyaneus (sulfadiazine, penicillin, streptomycin and aureomycin resistant). The renal function test showed 63 per cent phenolsulfonphthalein clearance. Stone analysis revealed calcium carbonate and phosphate.

Course.—In February 1944 roentgenograms showed bilateral large staghorn calculi; the patient was given amphojel,® 30 cc. four times a day. He had increasing dysuria and frequency. Roentgenograms showed no change; cystoscopy revealed cystitis. The blood urea nitrogen was 30 mg. per 100 cc., urea clearance 23 per cent and phenolsulfonphthalein 38 per cent. In March 1946 a left nephrolithotomy was performed. On April 14, 1950 roentgenograms showed no change in staghorn calculus on the right, no evidence of calculi on the left and bilateral minimal renal function. Urinary phosphorus excretion has averaged 250 mg. per day.

Case 2.—*History.*—J. C., a man aged 37, in 1938 had dysuria. In 1940 a left nephrolithotomy was performed. In 1941 he fractured his tibia and fibula; he was immobilized 10 weeks and calculi recurred. Then he had a left nephrolithotomy. In 1943 he had left nephrectomy, six months later a right nephrolithotomy and three months later a right nephrolithotomy. In 1945 he had staghorn calculus on the right, and a right nephrolithotomy was performed.

Laboratory Results.—The serum calcium level was 10.82 mg. and the serum phosphorus 3.30 mg., per 100 cc. The alkaline phosphatase determination was 2.6 Bodansky units and the total protein 7.6 Gm. per 100 cc. Urine culture grew P. vulgaris and A. aerogenes. Tests of renal function showed phenolsulfonphthalein excretion 93 per cent and urea clearance 55 per cent. Stone analysis revealed calcium phosphate plus carbonate.

Course.—In March 1945 the patient was started immediately postoperatively on a regimen of amphojel® therapy. At present he shows no roentgenographic evidence of calculi (Nov. 15, 1949). Results of treatment of this patient with various aluminum gels are shown in table 7.

COMMENT

Certain aspects of this therapeutic regimen seem to be well established by this study. It is evident that patients can take aluminum gels in amounts of 120 to 180 cc. daily for as long as seven years without experiencing untoward effects which could be attributed to this medicament. Constipation, when it occurred, was readily corrected by the judicious use of cathartics. There were no changes in plasma carbon dioxide content. Relief from dysuria with clearing of the urine was frequently reported, presumably as a result of the prevention of amorphous phosphate precipitation within the urinary tract. Most of the patients tolerated the medicament well. A few complained of some nausea and distaste at the beginning of treatment, but this disappeared on its continuation. There were individual preferences on the score of taste and consistency for each of the aluminum gels used, but after the introduction of basaljel® this basic aluminum carbonate gel has been almost without exception the preferred preparation.

With all preparations the objective of treatment could be achieved, namely, a significant reduction of urinary phosphorus. The most efficient on the basis of amount and aluminum content is basaljel.® In comparative studies it proved approximately 35 per cent more effective in lowering urinary phosphorus than the standard aluminum hydroxide gel preparation. However, the aluminum hydroxide tablets are often convenient to use because of their smaller bulk. In its effects on urinary phosphorus, each 0.6 Gm. aluminum hydroxide (amphojel®) tablet is equivalent to approximately 3.5 cc. of basaljel.® The time of administration of aluminum gels, one hour after meals and at bedtime, was chosen to secure the greatest efficiency with a given total dose.

TABLE 7.—*Correlation of Period of Aluminum Gel Therapy with Range of Laboratory Results in Case 2*

Date	Therapy	No. Determinations	Urinary Phosphorus Mg./24 Hr.	Urinary Calcium Mg./24 Hr.	Urinary Creatinine Gm./24 Hr.
5/11/45 to 1/18/46	Amphojel,® 40 cc. q.i.d.	5	0 to 286	58 to 161	1.48 to 1.96
1/18/46 to 4/12/46	Amphojel,® with magnesium trisil., 40 cc. q.i.d.	3	224 to 390	92 to 116	1.58 to 1.96
4/12/46 to 10/25/46	Amphojel ® tablets, 10 q.i.d.	2	238 to 442	96 to 152	1.37 to 1.89
10/25/46 to 11/ 3/47	Amphojel,® 40 cc. q.i.d.	7	201 to 394	66 to 133	1.33 to 1.60
11/ 3/47 to 1/ 8/48	Basaljel,® 20 cc. q.i.d.	1	197	69	1.38
1/ 8/48 to 4/ 3/48	Basaljel,® 30 cc. q.i.d.	2	183 to 347	53 to 74	1.42 to 1.45
4/ 3/48 to 9/12/48	Amphojel ® with magnesium trisil., 40 cc. q.i.d.	3	194 to 332	45 to 68	1.28 to 1.40
9/12/48 to 4/ 4/50	Basaljel,® 30 cc. q.i.d.	9	96 to 290	54 to 133	1.23 to 1.56

The dietary part of this regimen has its basis in the fact that the extent to which aluminum phosphate formation takes place in the intestinal tract to reduce urinary phosphorus excretion is dependent on the quantitative relationship between the phosphorus intake and the dosage of aluminum gel. Hence, with a fixed phosphorus intake at any given level, the aluminum gel dosage can be adjusted to achieve any desired urinary phosphorus excretion, even to the extent of its complete elimination. The chief problem, therefore, is one of gaining the patient's cooperation in having him follow a diet with a constant phosphorus content. This is most readily achieved with a menu which is flexible enough to conform with food habits and accessibility. These criteria are satisfied by the moderately low, constant phosphorus diet used in this study which also meets optimal dietary standards in other respects.

Since the effectiveness of this regimen is dependent on the constancy of both the diet and the medication, the only way to ascertain how faithfully it is adhered to is by frequent determinations of the 24-hour urinary phosphorus excretion. The importance of this check for achieving the objective of the therapeutic regimen cannot be overemphasized. Additional evidence has been provided in this study also for the manner in which aluminum gels lead to a lowered urinary phosphorus excretion. Freeman and Freeman [6] had earlier shown the striking fall in serum inorganic phosphorus resulting from the administration of aluminum gels in renal disease with hyperphosphatemia. With the subjects in our series who had normal renal function, values for fasting inorganic serum phosphorus were not significantly changed by aluminum gel therapy. When analyses were made throughout the day, during the period over which an aluminum gel was administered, a distinct lowering of the serum inorganic phosphorus level was regularly observed, as compared with control observations. This would provide a smaller load of phosphate ion to the renal tubules and permit its more complete tubular resorption. If these lower average serum inorganic phosphorus values depress parathyroid activity during aluminum gel administration, the depression is extremely brief and readily reversible, even after continuous therapy of many years' duration, as indicated by the rapidity with which the original serum and urinary phosphorus values return on discontinuation of therapy.

With respect to other possible deleterious metabolic effects of continuous aluminum gel administration, balance studies would suggest that none of any consequence occur.[11] The patients remain on positive phosphorus balance with this dietary intake. Transient increases in urinary calcium excretion are occasionally observed as well as a negative over-all calcium balance of minor magnitude. With more chronic administration of aluminum gels there is generally no significant increase in urinary calcium output over control levels. No demineralization of the skeleton has been observed, nor were there any appreciable changes in the serum calcium or alkaline phosphatase levels.

The evaluation of the therapeutic results should be tempered by an appreciation of the relatively small number of patients included in this study. These patients were selected with a view to enhancing the evaluation of a small series. A high percentage had required frequent operative intervention, and in more than half of the cases there was gross infection of the urinary tract of the type favorable to stone recurrence. When one makes allowance for the variable incidence of phosphatic calculus recurrence reported with other therapeutic procedures, the results with aluminum gel therapy in this series appear to be distinctly superior. In the 22 patients studied there were 36 kidneys which had been sites of previous phosphatic calculi or had stones present at the time treatment was instituted. There were no recurrences in the six kidneys from which the calculi had previously been removed; and in only three of the 30 kidneys with stones in situ was there any increase in the size of the stones: this was of small magnitude and not progressive. Stones were passed completely from four kidneys and reduced in size in three. In contrast with these favorable results is the experience with four patients who voluntarily discontinued therapy. In all four, stone growth of such magnitude occurred as to require operative removal.

---

[11] Shorr, E., and Carter, A. C.: Unpublished data.

Uncertainty still exists as to the minimal levels of urinary phosphorus excretion necessary for these therapeutic effects. Twenty of the 22 patients had an average 24-hour urinary phosphorus output below 500 mg. In this group, 3 patients had a small increase in the size of the stone. In one the increase began during a six month period in which aluminum gel therapy was inadvertently discontinued. In each instance there has been no further increase during the past 12 months. In the two patients whose 24-hour output of phosphorus ranged between 600 and 800 mg. there was no change in the size of the stone. Both these patients had uninfected urines.

It is evident that a number of factors are involved in establishing the critical level for urinary phosphorus which would protect against phosphate precipitation. Among these are the calcium and citric acid content of the urine, the 24-hour urine volume, the presence of infection with alkalinizing organisms, the condition of the renal pelvis and the existence of anatomic interference with free emptying of the pelvis. More extended experience will be required for the proper evaluation of all these factors as they bear on the levels of urinary phosphorus necessary to prevent recurrences.

Although for the purposes of the present study it was considered undesirable to introduce other variables, such as chemotherapeusis, a highly daily urinary output, ureteral dilation and other surgical procedures, these should also be employed, whenever appropriate, as adjuvants to aluminum gel therapy. It is also not certain how long therapy should be continued. With stones in situ and in the presence of urinary tract infection or stasis, the situation would seem to call for continuous therapy until the underlying condition is corrected. However, with a calculus-free and otherwise normal kidney, it is not unlikely that therapy need not be continued for as long as in the present study. Observations are now in progress on the effects of discontinuation of aluminum gel therapy in the suitable patients in the present series.

This therapeutic regimen is not intended to replace surgical intervention, when indicated; indeed, with the greater assurance which this regimen seems to provide against stone recurrence, surgical removal with postoperative management by aluminum gels would appear to be the preferable approach. The preoperative and immediate postoperative use of aluminum gels has been found by Dr. Victor F. Marshall of the Department of Urology of the New York Hospital to carry with it the advantage of preventing the rapid reformation of phosphatic precipitates in the urinary tract and drainage tubes; this procedure is now routinely employed on his service.

This regimen should also be considered as an adjuvant for the management of conditions requiring enforced immobilization, with its hazard of phosphatic stone formation in the urinary tract. One such study with a group of paraplegics has been made by Satterthwaite,[12] who reported almost complete protection against calculus formation by this regimen, when used in conjunction with postural drainage. Finally, its use may be recommended in systemic conditions, such as hyperparathyroidism in the absence of operative correction, and as an adjuvant in the management of other types of stones. Thus, when alkalinization is resorted to in persons who are uric acid or cystine stone formers, it is not uncommon for this procedure to lead to phosphatic stone formation. Coprecipitation of phosphates with calcium oxalate is also reported to occur with regularity when calcium oxalate stones become larger than 100 mg.[13] The reader is referred to another publication from this laboratory for a more detailed discussion of the physicochemical factors involved in the solubility of calcium and phosphate ions, and their bearing on the present therapeutic regimen.[5]

CONCLUSIONS

The rationale for the use of aluminum gels in the management of renal phosphatic calculi has been discussed. Reducing urinary phosphorus excretion should serve to prevent the precipitation of the relatively insoluble phosphate ion as the calcium, magnesium or ammonium salt. The usefulness of aluminum hydroxide gels for this purpose has been investigated in a series of 22 patients receiving a constant, moderately low phosphorus diet. Therapy was continued for periods of two to seven years. A variety of aluminum gel preparations were employed, of which basic aluminum carbonate gel (basaljel®) proved the most efficient in reducing urinary phosphorus excretion. The amounts of aluminum gel employed by us in these patients were well tolerated and without harmful effects. The details of the aluminum gel and dietary regimens are given, and emphasis is placed on frequent 24-hour urinary analyses for phosphorus in the control of this therapeutic procedure. Mechanisms leading to the reduction of urinary phosphorus excretion by aluminum gels are discussed. Unlike acidifying agents, aluminum gels are not limited in their effectiveness in the presence of urinary tract infection with ammonia-forming organisms, nor do they introduce the hazard of acidosis when renal functional impairment exists. The therapeutic results in this series of 22 patients are regarded as highly favorable, to judge from the absence of recurrences in six kidneys which were the sites of previous stone formation and from the fate of the stones in 30 kidneys which contained calculi at the time treatment was instituted.

Incidence of Leukemia Among Physicians.—Hardly a patient enters a hospital in this country these days, without being exposed to x-rays once or many times. The great value of such procedures cannot be questioned, as undoubtedly the information derived from such diagnostic procedures is life saving in many instances. Second, it has been clearly established that leukemia is more likely to develop in radiologists who are repeatedly exposed to this agent. This had been emphasized by Dunlap, who collected from the literature 24 cases of leukemia in those who were exposed to x-ray for long periods. Furthermore, Henshaw and Hawkins reported that leukemia is recognized approximately 1.7 times more commonly among physicians than among the white male population. They emphasize that their findings are in accord with the experimental observation on animals that exposures to roentgen rays cause an increase in the incidence of leukemia. Of even greater significance is the report of Ulrich, who studied over 34,000 obituary notices of physicians appearing in The Journal of the American Medical Association between the years 1935 and 1944. He observed that the incidence of leukemia among 205 physicians listed as radiologists was 3.9 per cent, which is more than eight times as great as the incidence (0.44 per cent) among those not listed as radiologists. This observer believes that this rather striking difference is substantial evidence that exposure to x-ray is a potential cause of leukemia.—Cyrus C. Sturgis, An Evaluation of the Nature, Treatment, and Prognosis of Leukemia, *The Proceedings of the Institute of Medicine of Chicago,* Oct. 15, 1950.

Clinical Notes, Suggestions and New Instruments

BILATERAL TESTICULAR TUMORS FOLLOWING BILATERAL ORCHIOPEXY

GUSTAVE KAPLAN, M.D.
and
BERNARD ROSWIT, M.D.
Bronx, N. Y.

The incidence of malignant neoplasms in undescended or ectopic testicles is high. Hinman and Benteen[1] reported an incidence of 7.5 per cent in cryptorchids and stated that tumors occurred 20 times as frequently in undescended testes as in those normally placed. Pace and Cabot[2] sectioned 24 testicles removed from the abdomen and detected microscopic evidence of cancer in three. Gilbert and Hamilton[3] reviewed 7,000 recorded cases of testicular tumors and found 840, or 11 per cent, associated with ectopia, a correlation 48 times higher than expected by chance.

Orchiopexy is not necessarily an effective prophylactic measure against the development of malignant degeneration. Gilbert and Hamilton[3] indicated that 77 tumors occurred in testes previously transferred to the scrotum from an ectopic position. Gilbert[4] analyzed the cases of 58 of a total of 65 patients (two of his own) reported on in the literature in whom malignant testicular tumors developed after orchiopexy.

Following is a report of a patient in whom bilateral testicular tumors developed subsequent to bilateral orchiopexy.

REPORT OF CASE

The patient was a white man aged 41, whose illness dated back to October 1945, at which time he noted a feeling of discomfort in his right testicle, which had begun to enlarge. At the age of 14 the patient had undergone a bilateral operation for cryptorchidism. The right testicle was brought down entirely within the scrotum while the left could be brought down only to the scrotoabdominal junction at the external ring. Physical examination revealed an enlarged right testicle, the size of a golf ball. On October 17 a right orchiectomy was performed. The pathological diagnosis was "seminoma" (fig. 1). Subsequently, postoperative irradiation was given. The lower retroperitoneal node-bearing area received a depth dose of 2,300 r and the upper retroperitoneal node-bearing area received 2,900 r. The depth dose to the right inguinal region was 2,000 r. All therapy was given over a period of 71 days. The following factors were used: 220 kv., 15 ma., Thoraeus filter, half-value layer 2 mm. Cu. and 50 cm. skin-target distance. The size of the abdominal field was 10 by 15 cm. and that of the inguinal region 6 sq. cm. Roentgenograms of the chest and excretory urograms showed normal conditions.

The patient was readmitted in November 1949, because of swelling in the left inguinal area which he first noted approximately six weeks prior to admission. There was no associated pain or tenderness. Physical examination revealed the absence of the right testicle. A large, hard, fixed mass, the size of a small plum, involved the left testicle in the area of the external ring.

On November 25 a left orchiectomy was performed. At operation an irregular testicular mass was observed lying within the inguinal canal. The tumor mass was bound down in firm scar tissue. The cord structures were thickened and indurated with invasion of tumor tissue, and the presence of tumor involving small lymph nodes was noted. The testicular tumor mass was freed and removed with the cord.

The microscopic diagnosis was "complex teratocarcinoma with choriocarcinoma" (fig. 2).

On December 15 approximately 10,000 mouse units of chorionic gonadotropin per liter of urine was reported. On December 18 a roentgenogram of the chest showed metastatic nodules in both lower lung fields. The excretory urogram was normal. In view of the absence of symptoms, the presence of metastatic nodules in the lungs and the radioresistance of the underlying disease, roentgen therapy was not deemed advisable.

COMMENT

Undescended testicles must always be considered from the viewpoint of potential malignancy. Orchiopexy does not prevent malignant change, nor does it decrease its incidence. Its value lies in providing an opportunity for close observation of a testicle in which the incidence of malignant neoplasia is high. Orchiopexy also encourages spermatogenesis and permits the repair of hernias that accompany cryptorchidism.

SUMMARY

The case of a patient in whom bilateral testicular tumors of different histological varieties developed after bilateral orchiopexy is presented.

REVERSAL OF AMINOPTERIN AND AMETHOPTERIN TOXICITY BY CITROVORUM FACTOR

EMANUEL B. SCHOENBACH, M.D.
EZRA M. GREENSPAN, M.D.
and
JACOB COLSKY, M.D.
Baltimore

The potent folic acid antagonists, aminopterin (4-amino folic acid) and amethopterin (4-amino-N^{10}-methyl folic acid) are being extensively employed for the amelioration of certain types of leukemia and other neoplastic diseases.[1] These antimetabolites induce a folic acid deficiency, manifested in patients by gastrointestinal cramps, diarrhea, hemorrhage, ulceration of the palate and oral mucous membranes, leukopenia, which may progress to an aplastic anemia, and alopecia. The appearance of these toxic manifestations may be delayed, and the cumulative toxic dose of drug may be exceeded before signs of toxicity become evident. For this reason, the dosage employed of these amino-substituted derivatives of folic acid is often less than that necessary for therapeutic efficacy. These toxic manifestations have not been reversible clinically when folic acid, liver extract or vitamin B_{12} has been administered. Experimental observations have demonstrated that under certain specific conditions folic acid can completely prevent but not reverse both the toxic[2] and the antineoplastic effects[3] of these antimetabolites in mice. However, when folic acid was administered simultaneously with or after injections of aminopterin, no protection from the lethal toxicity of the latter compound was evident,[2] regardless of the route of drug administration.

The failure to reverse these toxic manifestations of induced folic acid deficiency with folic acid has been a distinct deterrent to the optimal administration of the anti-folic-acid preparations, despite the accumulated evidence that they are beneficial in the treatment of certain forms of leukemia.

A new growth factor[4] necessary for the growth of the bacillus Leuconostoc citrovorum, designated as the "citrovorum factor," has recently been reported to prevent the toxicity of aminopterin in mice and rats.[5] The anti-folic-acid compounds may inhibit the conversion of folic acid into a metabolically more active compound, which is, or closely resembles, the citrovorum factor. When citrovorum factor was administered simultaneously with, or even subsequent to, lethal doses of aminopterin, we observed complete protection from the toxic manifestations in mice, in contrast to observations on the inefficacy of folic acid in these circumstances.[6] No studies on the effect of citrovorum factor on established toxic reactions in man have been reported.

REPORT OF CASES

CASE 1.—A 56 year old Negro man was subjected to a midthigh amputation of the left leg in April 1950 for a leiomyosarcoma in the upper fibula region. Several weeks thereafter, roentgen examination of the chest disclosed parenchymal shadows in the lungs, which were interpreted as multiple pulmonary metastases. Roentgen therapy, to a total of 2,000 r to each of four chest ports, was administered over a period of 3½ weeks, without any symptomatic or objective response.

On June 21, oral amethopterin therapy was begun. The patient received 10 mg. daily. On the ninth day of treatment, when a total of 90 mg. had been administered, he complained of a burning sensation in the mouth. Drug therapy was continued with the same daily dose. Three days later, after he had received a total of 120 mg. of amethopterin, superficial ulcerated lesions of the buccal mucosa, the right part of the hard palate and the gingival margin appeared. The white blood cell count, which had been 4,600 cells per cubic millimeter prior to treatment on June 21, fell progressively so that by July 3, the total count was 2,100 per cubic millimeter. The dosage of amethopterin was continued unchanged. The ulcerated lesions became somewhat more extensive and painful and assumed a typical appearance, with a central grayish membrane surrounded by a hemorrhagic zone. Each ulcer was 5 to 10 mm. in diameter. No gastrointestinal or hemorrhagic manifestations were present. On July 7, the total leukocyte count was 2,450 per cubic millimeter, with a distribution of 84 per cent neutrophils, 12 per cent lymphocytes, 2 per cent eosinophils and 2 per cent monocytes. Results of other hematological and chemical studies of the blood were unchanged when compared with those of the period preceding anti-folic-acid therapy.

An attempt to evaluate the ability of citrovorum factor to reverse these amethopterin-induced lesions was initiated on July 9, after the patient had received a total dose of 180 mg. during the preceding 18 days. The dosage of amethopterin was maintained unchanged, and 40,000,000 units of citrovorum factor (synthetic)[7] was administered intramuscularly daily. Each milliliter contained 20,000,000 citrovorum factor units, which represent an equivalent of 7.0 mg. of folic acid by microbiologic assay. The citrovorum factor was dissolved in 0.8 per cent sodium chloride solution containing 0.01 M phosphate buffer at p_H 7.16.

The patient received the combined treatment with amethopterin and citrovorum factor for a total of seven days. On the third day of this regimen, the ulcers appeared to be somewhat smaller and the patient experienced less pain. Further regression of the ulcers was noted on the fourth day, followed by complete healing after the fifth day of citrovorum administration, despite the continued daily ingestion of 10 mg. of amethopterin. The use of citrovorum factor was discontinued two days thereafter, but the amethopterin dosage was maintained. The total white blood cell count on the sixth day of the combined regimen was 4,200 per cubic millimeter, with no significant alterations in the differential count. Ten days after the administration of citrovorum factor was discontinued, the return of typical mouth lesions induced by folic acid antagonists was observed. No effect on the neoplastic lesions was observed during the administration of amethopterin, either alone or combined with the citrovorum factor.

The citrovorum factor (synthetic) was supplied by the Lederle Laboratories Division, American Cyanamid Company, Pearl River, N. Y.

From the Department of Preventive Medicine, the Johns Hopkins University School of Medicine, and the Clinical Research Unit, National Cancer Institute, United States Marine Hospital.

These investigations were aided in part by a grant to the Department of Preventive Medicine *from the American Cancer Society recommended* by the Committee on Growth, National Research Council.

Figures 1 and 2 represent the appearance of the palate on the seventeenth day of amethopterin therapy and 10 days later, after 280,000,000 units of citrovorum factor had been administered over a period of seven days The amethopterin dosage had been maintained unchanged

Case 2—The patient was a 48 year old white woman who had undergone a radical mastectomy for a neoplasm of the right breast in September 1945 In 1948 metastases to the left pleura occurred, with massive recurrent sanguineous effusion in which malignant cells had been observed on several occasions Numerous thoracenteses had been performed, with prompt reaccumulation of the fluid and persistence of symptoms From Nov. 9, 1949 through Jan 24, 1950, the patient had received amethopterin daily except for a one week interruption because of toxic manifestations The total amount of drug administered was 490 mg. During this period, the effusion disappeared and the patient improved symptomatically She was discharged from the hospital without further medication on Feb 6, 1950

She was readmitted to the Clinical Research Unit of the National Cancer Institute on May 2, because of pain in the left region of the thorax. At this time, roentgenologic examination showed a solid nodular lesion on the pleura of the left lung at the level of the fifth rib in the anterior axillary line She was treated with an oral preparation of aminopterin, 2.0 mg daily, from May 17 to May 31. On May 27 she noted soreness of the tongue and buccal mucosa. Four days later the typical buccal, palatal and gingival ulcerations associated with folic acid antagonist therapy were noted. These ulcerations healed in approximately five days following discontinuation of aminopterin therapy.

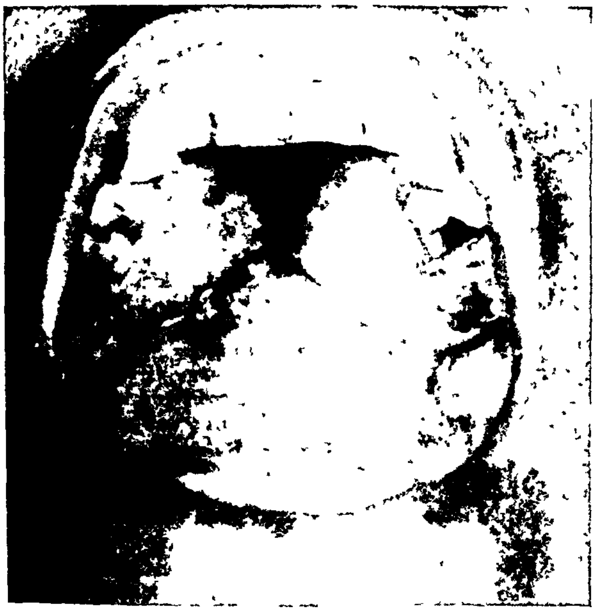

Fig 1 (case 1)—Ulcerations on the right part of the hard palate and gingival margin after the patient had received 170 mg of amethopterin over a 17 day period

The administration of aminopterin was resumed on June 22, with daily doses of 1.0 mg. This dosage was well tolerated, and so on July 3 it was increased to 1.5 mg daily On July 6 the buccal mucosa was noted to be erythematous, and two days later the oral ulcerations reappeared Use of aminopterin was discontinued for one week and resumed on July 15 with a smaller daily dose, so that she received 5.0 mg. a week. The influence of estradiol (20,000 units a day intramuscularly) on the toxic manifestation of aminopterin was studied. When the doses of aminopterin were again increased to 1.5 mg a day and given with the estrogen therapy, oral ulcerations reappeared After an interval of several days, the folic acid antagonist therapy alone was resumed at the lower dosage. On August 28 the doses of aminopterin were increased to 2.0 mg a day administered intramuscularly. One hour prior to each injection of the aminopterin, 15 mg. of the sodium salt of folic acid was injected However, on September 4 stomatitis with mucosal ulcerations appeared On September 5 the amount of folic acid was increased to 75.0 mg. a day, with no detectable improvement of the buccal and palatal ulcerations. In addition, severe dysphagia, anorexia and alopecia became manifest. Beginning September 8, citrovorum factor, 20,000,000 units a day, was administered one hour prior to each dose of aminopterin. No improvement of the stomatitis was apparent, and so after four days (September 12) the doses of citrovorum factor were increased to 40,000,000 units

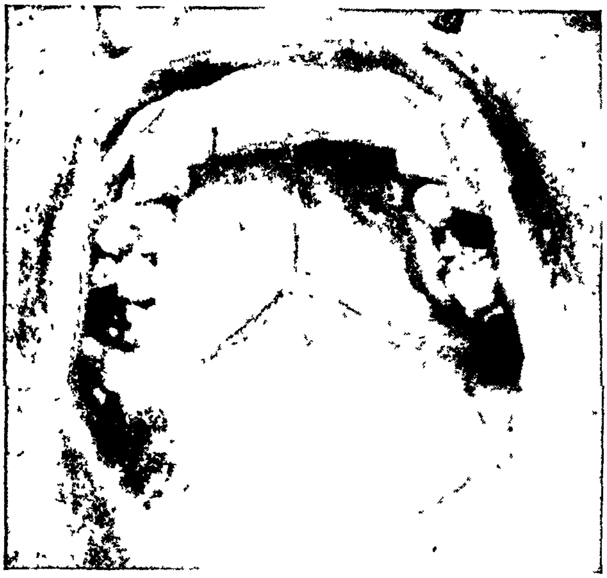

Fig 2 (case 1)—Appearance of palate with complete healing of ulcerations 10 days later, when 280,000,000 units of citrovorum factor concentrate had been administered over a period of 7 days Amethopterin had been continued, and the patient had received a total of 270 mg at this time

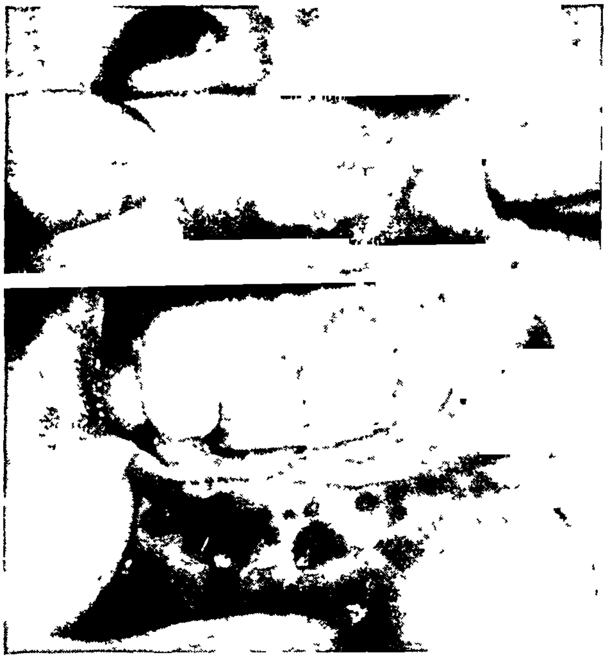

Fig 3 (case 2)—Ulcerations of the oral mucosa as they appeared on Sept 8, 1950 The patient had been receiving 2.0 mg of aminopterin daily

a day. The administration of aminopterin, 2.0 mg. a day, was not interrupted during this period. On September 15 subjective improvement was noted by the patient, and the ulcerations were completely healed by September 18. The administration of citrovorum factor was discontinued, although the parenteral injection of aminopterin was maintained at the same dosage. Ten days later, the ulcerations of the palate, pharynx and buccal mucosa reappeared and the administration of aminopterin was discontinued.

Repeated hematological examinations were performed during this period. A mild leukopenia, with 3,000 to 4,000 cells per cubic millimeter, was observed during the episodes of aminopterin toxicity, which promptly returned during the intervening periods to the pretreatment level of 5,000 to 7,000 cells per cubic millimeter. The differential leukocyte distribution was unaltered. No anemia or hemorrhagic manifestations were noted, although a slight macrocytosis was evident. The appearance of the pleural metastasis was not significantly changed during this period of observation.

The regression of the ulcerations on the palate and buccal mucosa of both patients, despite the continued administration of amethopterin or aminopterin, was striking. The ulcerations appeared to clear more rapidly under this combined therapy than with discontinuation of the folic acid antagonist without the addition of citrovorum factor. The knowledge that citrovorum factor is capable of relieving the toxic manifestations that are caused by the folic acid antagonists should permit more efficient utilization of these latter experimental antineoplastic agents.

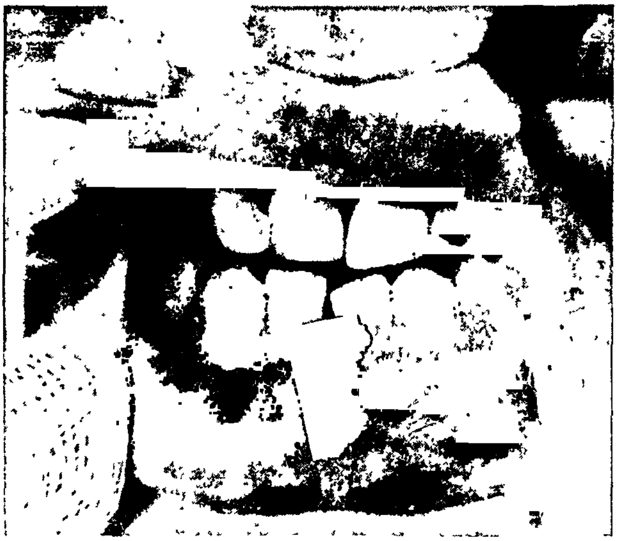

Fig. 4 (case 2).—Appearance of the mucosa 10 days later with healing of the ulcerations. Aminopterin dosage had been maintained unchanged. Citrovorum factor had been administered from September 8 to September 18 in doses of 20,000,000 to 40,000,000 units daily

SUMMARY

In two patients who had received amethopterin or aminopterin for therapy of metastatic neoplasm leukopenia and ulcerated mouth lesions developed. They were treated with citrovorum factor, without discontinuation of the daily dosage of the anti-folic-acid compound. The mouth lesions promptly healed, and the leukopenia disappeared. The reversal of these toxic manifestations by citrovorum factor may be a distinct clinical aid when the folic acid antagonists are employed for the therapy of selected neoplastic states. Our observations in experimental animals and experience with these patients indicate that citrovorum factor, in contrast to folic acid, is able not only to prevent but also to reverse some of the established toxic manifestation of the potent folic acid antagonists, aminopterin and amethopterin.

TREATMENT OF SCLERODERMA WITH PROCAINE

Report of Cases

J. P. TURNER, M.D
Goshen, Ind.
and
F. R. SCHMIDT, M.D.
Chicago

Four patients with scleroderma were treated with multiple intravenous infusions of 0.1 and 0.2 per cent solutions of procaine hydrochloride over a period of several months. A rapid and dramatic improvement was observed in the first patient within 72 hours after this treatment was instituted. The improvement has persisted in this patient as well as in the other three.

REPORT OF CASES

Case 1.—L. S., a white man aged 60, was first seen on Oct. 18, 1949, complaining of slowly progressive and generalized thickening, hardening and discoloration of the skin. He stated further that he had been bothered with recurrent ulcerations and scarring of the tips and bony prominences of the joints of the fingers of both hands and an ulcer on the right foot. In addition, he complained of progressive hoarseness, difficulty in opening his mouth and chewing, inability to use his hands and shortness of breath on exertion. He also had swelling of the ankles and a cough that was productive of sputum. All these symptoms had been present from one to two and one-half years. From Aug. 16 to Oct. 17, 1949, this man had been a patient in another hospital but the skin, the joints and the ulcers had not responded to therapy consisting of application of ointments and bed rest. The family history and his past medical history were noncontributory.

Physical examination revealed a well developed and well nourished white man, slightly dyspneic, with masked facies and a generalized bluish bronze color of the skin. The mucous membrane of the mouth appeared thickened and hyperkeratotic, especially over the pharynx and hard palate. There were moist rales present in the lower lobes of both lungs. The left border of cardiac dulness was at the anterior axillary line. There was a loud, harsh systolic apical murmur transmitted to the axilla and anterior chest wall. The liver was palpable 3 cm below the right costal margin. The fingers of both hands presented a tapered appearance and were semiflexed and practically immobile. The skin over the fingers was reddish blue, shiny, hard to the touch and bound down to the subcutaneous tissues.

The patient was unable to approximate the thumb and forefinger or flex the tips of the digits to the palms. There were a few small ulcerations on the dorsa of the hands over the bony prominences, especially at the metacarpal-phalangeal areas. The creases on the palmar surfaces of the fingers were ironed out. The skin of the trunk, arms, forearms, thighs and legs was bluish bronze, indurated and difficult to pick up between the fingers. There was a marked pitting edema of the feet, ankles and legs. A cratered shallow ulcer 3 cm. in diameter was present on the medial aspect of the right foot.

The microscopic findings confirmed the clinical diagnosis of scleroderma. Results of a biopsy of the skin from the region of the elbow showed generally short rete pegs and a narrow granulosa layer. The underlying dermis was composed of closely arranged collagenous connective tissue fibers showing a tendency toward fragmentation, and the blood vessels were surrounded by a scanty collar of round cells. The Kahn reaction of the blood was negative. The urine showed normal findings. The serum proteins were 6.15 mg., with an albumin-globulin ratio of 1.5 to 1. The serum calcium was 9.5 mg The red blood cell count was 4,100,000, with a hemoglobin value of 12.4 Gm. The white blood cell count was 12,900. The chest roentgenogram showed a 30 per cent cardiac enlargement, with a tortuous sclerotic aorta and increased bronchovascular markings in the lower lobes consistent with passive pulmonary congestion. The electrocardiogram was abnormal but not

diagnostic. Examinations and several cultures of the sputum concentrate did not reveal acid-fast organisms.

The patient was first admitted to the surgical service, where the ulcer on the right foot healed under local treatment. He was then transferred to the medical service for further care, on Nov. 2, 1949. Since the patient had pain and limitation of motion of the interphalangeal and metacarpal-phalangeal joints of the hands, it was decided to give him intravenous infusions of procaine, following the suggestion of Graubard and Peterson.[1] He received from 0.5 to 0.8 Gm. of procaine hydrochloride with each infusion in a 0.1 to 0.2 per cent concentration in 10 per cent dextrose and water. A prophylactic dose of 0.1 Gm. of a barbiturate was given by mouth 30 minutes prior to each infusion.[2] On the day following the first infusion the patient reported that the itching of his feet had been relieved. After the third daily infusion the patient was able to approximate his thumb and forefinger and flex his fingers to the palmar surfaces and was able to use his hands for writing for the first time in one year. On the seventh day there was definite change in the color of the skin of the face, neck, chest, arms and hands, from the former bluish bronze hue to a pink-red color. The skin, particularly of the chest, was softer in texture and less taut. Because of the immediate response to this treatment it was continued, and an average of two infusions a week and a total of 26 were administered. The skin of the trunk, face, neck and hands has become progressively softer and more elastic, with the greatest improvement being noted on the skin of the trunk. The patient stated that his skin has been approaching its normal color and texture, with the exception of scattered areas of pigmentation. He has become less hoarse, and his expression has become more animated. He has been able to open his mouth wider and chew his food with more ease. The mucous membrane of the mouth, pharynx and pillars has assumed a more normal color and appearance. The ulcers on the bony prominences and tips of the digits have not healed completely. The cardiac decompensation has been controlled with digitoxin and the mercurial diuretics. There was no change in the serum calcium, serum protein or the albumin-globulin ratio.

Case 2.—M. M., a woman aged 50, a patient of Dr. R. Jaramillo, of Santiago, Chile, had been observed for six years. The patient had had increasing difficulty in the use of her fingers and legs. Her face had gradually assumed a mask-like expression, so that the skin of the face was tight, whitish and rigid. She began to have great difficulty in opening her mouth and in swallowing. Several ulcers on the lower legs had healed with scars. New ulcers had appeared on the slightest trauma. All the fingers were rigid and had lost their terminal phalanges. The skin on the back of the hands to a distance 5 cm. above the wrists was tight, fixed and hard. The skin of the lower third of the legs was tight, hard and scarred. There was an atonic ulcer with hard borders on the left leg at the level of the internal malleolus which measured 6 by 6 cm.

Daily infusions of procaine hydrochloride were given for 10 days. A total of 4.4 Gm. of the drug was administered. Biweekly infusions of 0.6 Gm. of procaine were then given for five weeks. The last seven injections were given intramuscularly because venipuncture was too difficult. The patient was able to move her hands with less difficulty after five infusions, and after nine treatments she could swallow more easily. Creases began to reappear on the back of the hands. Later the movements of the hands became much easier. No further improvement was noted during the remaining injections. She left the hospital on Sept. 8, 1950, feeling greatly improved.

Case 3.—E. P., a woman aged 35, a patient of Dr. F. Prats and B. Vaisman, of Santiago, Chile, had noticed an increase in the pigment of her hands and face in 1945. In 1949 the skin became noticeably thickened and the facial creases were obliterated. A diagnosis of scleroderma was made, which was confirmed by biopsy. Previous treatment had failed to stop the progressive limitation of the movements of the joints of the face and hands. Intravenous infusions of procaine hydrochloride in the manner described above were given, totaling 12 Gm. of the drug. This amount was administered over a period of 57 days. The elasticity, color and texture of the skin improved greatly. The mobility of the affected joints began to increase after the sixth infusion. During the last days of the treatment the patient complained of disturbances of hearing. She left the hospital feeling greatly improved and was to return for further treatment.

Case 4.—T. A., a woman aged 47, a patient of Dr. F. Prats and B. Vaisman, of Santiago, Chile, entered the hospital in February 1950 with a diagnosis of scleroderma and Norwegian scabies. The family history and her past medical history were noncontributory. The patient experienced great difficulty in standing, walking and swallowing due to fixation of the joints. After the scabies was cured, eight infusions of procaine hydrochloride were given on successive days until she had received 3.8 Gm. of the drug. The patient's appetite and general condition improved remarkably. The movements of her fingers and jaws grew easier after the fourth infusion. Following the eighth infusion the temperature rose rapidly to 103.1 F. This febrile episode was regarded as due to sensitization to the drug. All treatment was stopped. Two months later the patient developed a chill with high fever when procaine was used as a local anesthetic in obtaining material for a biopsy. Continued attempts to desensitize the patient to procaine with minute quantities injected intradermally failed. Nevertheless, the patient remained greatly improved.

COMMENT

There is always the possibility that the improvement in the first patient could have been due to a spontaneous remission. However, this seems unlikely when one considers that there was progressive improvement noted in the appearance of the skin and in the mobility of the joints throughout the treatment, whereas the ulcers over the bony prominences of the fingers did not seem to be favorably affected by the treatment. It is not likely that rest alone could have accomplished this response, since the patient had had a trial of bed rest for 60 days prior to admission to the hospital with no change in his condition. It is believed that the results of treatment in these cases are encouraging and warrant further investigation.

The infusions should be given slowly. An average of 30 minutes for each infusion is advisable.

SUMMARY

The report of four cases of scleroderma that responded favorably to intravenous infusions of 0.1 and 0.2 per cent procaine hydrochloride in solution are presented.

The remarkable improvement noted was in the color, texture and elasticity of the skin and mucous membranes, and increased mobility of the interphalangeal, metacarpal-phalangeal and temporomandibular joints.

There was no appreciable effect on the course of the ulcers over the bony prominences of the joints of the hand.

122 South Michigan Avenue, Chicago (13).

Standards, Usefulness, Nonsectarianism.—In order that a physician may best serve his patients, he is expected to exalt the standards of his profession and to extend its sphere of usefulness. To the same end, he should not base his practice on an exclusive dogma or a sectarian system, for "sects are implacable despots; to accept their thralldom is to take away all liberty from one's action and thought." A sectarian or cultist as applied to medicine is one who alleges to follow or in his practice follows a dogma, tenet or principle based on the authority of its promulgator to the exclusion of demonstration and scientific experience. All voluntarily associated activities with cultists are unethical. A consultation with a cultist is a futile gesture if the cultist is assumed to have the same high grade of knowledge, training and experience as is possessed by the doctor of medicine. Such consultation lowers the honor and dignity of the profession in the same degree in which it elevates the honor and dignity of those who are irregular in training and practice.

Council on Physical Medicine and Rehabilitation

REPORT OF THE COUNCIL

The Council on Physical Medicine and Rehabilitation has authorized publication of the following article on the recommendation of its Advisory Committee on Clinical Thermometry The Committee members are as follows George Crile Jr, M D, Eugene F DuBois, M D, Steven M Horvath, George Morris Piersol, M D, Chairman, John Talbott, and R E Wilson

Howard A Carter, *Secretary*

ORAL AND RECTAL TEMPERATURES OF MAN

STEVEN M HORVATH
H MENDUKE
and
GEORGE MORRIS PIERSOL, M D
Philadelphia

The so called normal body temperature of a healthy person has been stated categorically to be 98 6 F (37 0 C) Another clinically accepted truism is that the rectal temperature is 1 degree Fahrenheit higher than the oral, or approximately 99 6 F (37 6 C) These values are, of course, merely approximations and can, therefore, be highly misleading

The origin of these figures is somewhat obscure The following review of the literature is an indication that even the value 98 6 F for the oral temperature is undoubtedly incorrect Schaefer[1] summarized the oral temperatures obtained by a group of eight authors who published their material between 1848 and 1898 and found it to be 98 3 F Davy[2] in 1845 reported a mean value of 98 4 F for the oral temperature obtained during the working day, while Pembrey and Nicol[3] found it to be 97 2 F Allbutt,[4] who introduced the present day clinical thermometer, presented his mean value as 98 14 F The first statistical analysis of the oral temperature in man was performed by Whiting[5] The mean oral temperature of 500 criminals was 98 38 F, with a standard deviation of 0 486 Renbourn and Bonsall[6] studied 894 males living in the tropics and found a slightly higher mean oral temperature than was reported by Whiting,[5] their mean value being 98 75 F with a standard deviation of 0 50 A recent report by Carmichael and Linder[7] on 24 normal subjects indicated that the oral temperature between the hours of 8 and 9 a m was 97 8 F, and between the hours of 4 and 5 p m, 98 09 F Ivy[8] obtained the oral temperatures of 276 medical students who were attending class between the hours of 8 and 9 a m His mean figure was 98 1 F Reimann[9] has also reported two different groups of data on the oral temperature of man In his first study, the mean value was 98 2 F, and in the second the value was 99 0 F

Probably the basis for the present day standard of 98 6 F originated from the work presented by two different groups of authors Becquerel and Breschet[10] in 1833 found the mean oral temperature to be 98 6 F Wunderlich[11] undoubtedly compiled the most extensive data on this subject and reported a mean value of 98 6 F It is interesting to note that the mean of all the means reported from 1845 to 1945 turns out to be 98 34 F The range of the means reported is from 97 2 to 99 0 F

A similar discrepancy is observed in the differences between rectal and oral temperatures It is clear that the difference of 1 degree Fahrenheit between these two temperatures, generally accepted by laymen and physicians, does not take into account the data available in the literature

Bardswell and Chapman[12] reported a difference of 0 9 F Wunderlich[11] in his series reported a difference of 0 7 F Renbourn and Bonsall[6] have reported a difference of 0 7 F Carmichael and Linder[7] found the difference to be 1 03 in the morning and 0 82 in the afternoon The largest difference, 1 2 F, was reported by Pembrey and Nicol[3] Burton-Fanning and Champion[13] reported a difference of 0 4 F The textbooks of Best and Taylor and of Macleod report a mean difference of 1 0 F All these observations indicate not only that there is no clear statement of the relation of rectal temperature to the mean body temperature but that there are considerable discrepancies among the data presented by various workers It is also obvious from this review that there is considerable individual variation In view of this confusion it was considered that a controlled study on normal males and females might help to clarify some of the discrepancies that have been noted

METHODS

Thirty-eight females with a mean age of 23 years (range from 19 to 35 years) and 16 males with a mean age of 23 years (range from 21 to 37) were subjects for a measurement of rectal and oral temperatures during 1947-1948 and 1948-1949 This study was conducted during the months of October to January Calibrated clinical thermometers were used, and simultaneous measurements of both oral and rectal temperatures were made while the subjects were lying in bed The thermometers were in place for five minutes The measurement in the morning was made as soon as the subjects awoke, between 6 30 and 7 15 a m The observations in the evening were made again in bed immediately after they had retired, between 10 and 12 p m These subjects were all healthy and had had a physical examination within a month prior to the test, a follow-up examination being made at the completion of the tests

RESULTS

The range of observations extended over a period of 29 to 118 days for both male and female subjects The total number of observations on 38 females was 2,810, a mean of 74 observations on each The mean observations on males were 78, the total number of observations was 1 248 For purposes of statistical analysis the data of only the first 29 consecutive values were considered, since this was the smallest consecutive number obtained in the series Furthermore, since all subjects were included in the analysis, it was possible to have each receive equal weight in the distributions of the combined individual readings and combined means of subjects, i e, the mean of the individual means was equal to the mean of the combined individual values

Since some of the observers read to the closest fifth of a degree Fahrenheit while others attempted to read to the closest tenth of a degree Fahrenheit, the odd readings of the latter were distributed among the even readings in such a manner that the means were completely unaffected and the dispersions were affected negligibly, if at all One woman, who was obviously a very unusual subject, having rectal morning temperatures as high as 104 F, was eliminated from the analysis

For each subject in the experiment, six frequency distributions were set up:

(*a*) The first 29 rectal morning readings.
(*b*) All rectal morning readings.
(*c*) All rectal evening readings.
(*d*) The first 29 morning D's (where D is the difference in temperature between rectum and mouth, D = T(R) — T(M).
(*e*) All morning D's.
(*f*) All evening D's.

Throughout the remainder of this paper all temperatures will be given in Fahrenheit units unless otherwise specifically indicated, and the following notation will be used:

T(i), the mean temperature for a given subject.
T(m), the mean of all temperatures obtained for the men.
T(f), the mean of all temperatures obtained for the women.
D(i), the mean of the differences between rectal and oral temperatures for a subject.
D(m), the mean of the differences for men.
D(f), the mean of the differences for women.

For each of the distributions mentioned above, arithmetic means were computed for each subject. In addition, grand means for males and for females were computed (table).

In order to determine whether there was a significant difference between individual mean temperatures, T(i), of men and women with respect to the grand mean and the variability of the means, the following analysis was carried out. The mean of the temperatures for men, T(m), in the morning was 98.2 F.; the mean for the women, T(f), in the morning was 98.6 F. The difference was 0.4. The standard error of this difference was 0.15. When the "t" test familiar to statisticians was applied, it was found that t=2.7, and, with 46 degrees of freedom, the corresponding probability P=0.01. For such a value of P it is customary to conclude that the difference is significant; it follows that over this period of 29 days the mean morning temperature for women was higher than the mean morning temperature for men. In addition to having a higher mean temperature, women exhibited greater variability in their mean temperatures than did men. This was borne out by the following analysis. Variance of the means of men around the grand mean was 0.114; for women it was 0.254. "F"[14] was computed to be 2.23, with 33 degrees of freedom for women and 13 degrees of freedom for men. The probability was found to be between 0.01 and 0.05.

Mean Value for the Rectal Temperatures (F.) and Differences Between Rectal and Oral Temperatures (F.) Observed in a Group of Healthy Adult Males and Females

	Males		Females	
	Rectal (F.)	Difference	Rectal (F.)	Difference
First 29 morning.........	98.2	0.8	98.6	0.8
All morning..............	98.3	0.8	98.6	0.7
All evening..............	99.1	1.0	99.1	0.8

There were 11 men for whom both morning and evening readings were recorded. Of these, 10 showed higher evening than morning means and one showed no change. There were 33 women for whom both morning and evening readings were recorded. Of these, 28 showed higher evening than morning means, 2 showed slightly lower evening than morning means and 3 showed no change. The probability of as many as 10 increases of 11 subjects, if there were really no real difference between morning and evening readings, is only 0.005. For women, the probability is less than 0.001. Both men and women, therefore, have significantly higher mean temperatures at night than in the morning.

The difference between the rectal and oral temperatures for men, D(m), carried to two decimal places, was 0.84. The corresponding figure for women, D(f), was 0.76. The difference was 0.08 and the standard error of the difference was 0.11, giving a "t" value of 0.727. With 46 degrees of freedom the probability attached to "t" was between 0.4 and 0.5. Hence the hypothesis of no real difference between the sexes with respect to the morning D may be accepted. (Even if the difference were highly significant statistically in this case, it would still not be important clinically since it is too small to be helpful.)

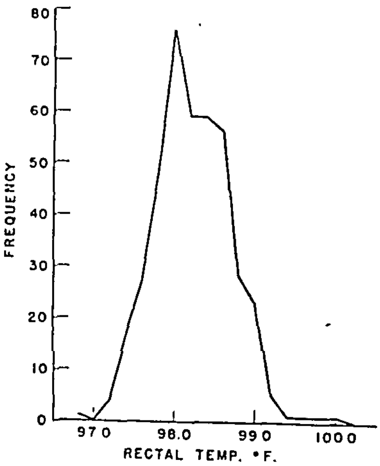

Fig. 1.—Distribution of morning rectal temperatures of male subjects. This curve and those in figures 2, 3 and 4 represent the values obtained during the first 29 consecutive days of observation on each subject.

The estimated variance of D(i) for men was 0.0982; for women it was 0.1309. "F" was found to be 1.332, and, with 33 degrees of freedom for women and 13 for men, the difference in variances was not significant at the 0.05 level. Hence the hypothesis of no real difference between the sexes with respect to variability of morning D(i) may be accepted. As a rough measure of variability, the range was found for each subject for the first 29 rectal morning readings and for the first 29 morning rectal-oral differences. The mean range of rectal temperatures in males was 1.2 F. and in females 1.5 F. The mean range of differences between rectal and oral temperatures was 1.0 F. for males and 1.4 F. for females.

Further analysis of the data was restricted to the first 29 morning values. There was no observable difference between the results obtained from the first 29 and from all the morning values with respect to any of the means. Furthermore, the morning readings of temperature were secured under more controlled and constant conditions. Distributions of morning rectal temperatures and of D's were set up, by sex, for the first 29 morning readings of all subjects combined. The graphs of these distributions are shown in figures 1 through 4.

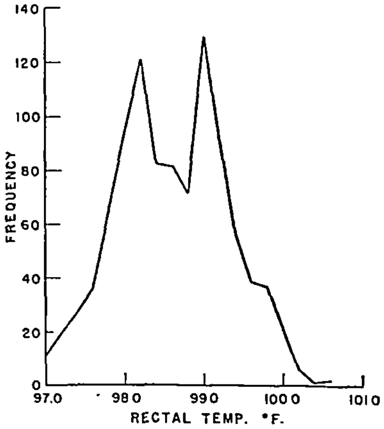

Fig. 2.—Distribution of morning rectal temperatures of female subjects.

Figure 1, illustrating the rectal morning temperatures of males, is unimodal, with a peak at 98.0 F., but is skewed slightly to the left. Normal curves were fitted to the actual distributions of male temperatures, male morning D's and female morning D's and goodness of fit was then tested.[15]

On fitting a normal curve to the distribution of combined rectal morning temperatures of all males, the probability of chi-square was between 0.1 and 0.2. While this is a rather low probability, it is not low enough to warrant rejection of the hypothesis of normality and, therefore, the hypothesis of normality was accepted. Hence it might be concluded that the mean rectal morning temperature of males is 98.2 F., with a standard deviation of 0.47 F., and 68 per cent of all individual readings would lie within the limits of 98.2 plus or minus 0.94, and 99.7 per cent, or practically all, would lie within the limits of 98.2 plus or minus 1.41. This would not, however, be particularly enlightening unless persons did not differ significantly in their individual means and in their individual variances. If individuals do differ signficantly, there would be little value in considering a universe of temperatures without regard to specific subjects.

---

[14] The measure of variability used here is the estimated population variance, where that variance is the mean square deviation from the sample mean (i. e., standard deviation squared) adjusted for degrees of freedom. "F" is the ratio of the larger estimated variance to the smaller. As in the "t" test, there is a given degree of probability attached to "F" for a given number of degrees of freedom. It is customary to conclude that the difference in variance is significant if this probability is less than 0.05.

A further hypothesis was therefore established, i. e., that there is a single universe of temperature values for all men and that *the mean temperature of each person represents a sample* taken at random from that universe. Under this hypothesis, the standard error of the mean for samples of size 29 was computed to be 0.087 F. If the individual means indeed represented random samples taken from the same universe, then only 0.3 per cent of the means should have been more than 3 standard errors away from the grand mean. Four of the 14 means, however, were more than 3 standard errors away from the mean (almost 29 per cent instead of the theoretical 0.3 per cent). The hypothesis that there is a single normal morning temperature for all healthy men was, therefore, rejected.

The L_1 test[16] was applied to see whether there was homoscedasticity among subjects, i. e., do persons all have the same variance in temperatures? The value of L_1 for 14 samples of size 29 was 0.668, which gave a probability of less than 0.01. Two subjects could be considered "extreme," but even after their variances were eliminated the probability was still less than 0.01 It may be concluded, therefore, that men differ in the variability of their individual readings; i. e., there is no single "normal range" of temperatures applicable to all men.

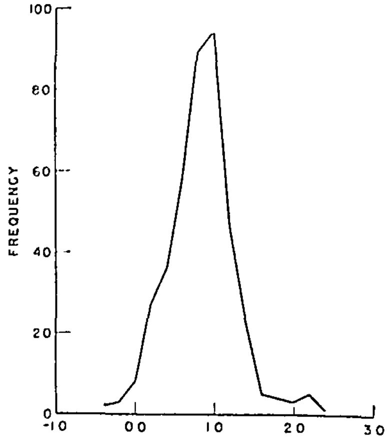

Fig 3.—Distribution of the differences between rectal and oral temperatures of male subjects

The distribution of rectal morning temperature readings of all females combined (fig. 2) was definitely bimodal, with one peak at 98.2 F. and another at 99.0 F. Both peaks are approximately the same height, indicating the possibility of two phases of temperature of roughly equal duration for each woman over a period of 29 days, i. e., a menstrual cycle. It is indeed statistically possible that each woman shows homogeneous temperature readings during the cycle and, therefore, that there are two distinct groups of women. Inspection of the individual distributions of readings for women, however, showed evidence of two peaks in a large number. Since the bimodal nature of the distribution made the fitting of theoretical curves a useless procedure, no further analysis was undertaken.

Figures 3 and 4 show the distribution of the first 29 D's for men and for women, respectively. Both are unimodal, with a peak for each at 1.0 F., and both are skewed to the left. Normal curves were fitted to each. For the male morning D observations, the probability of chi-square was between 0.01 and 0.001, and for the female morning D's it was less than 0.001. In both cases, the hypothesis of normality would conventionally be rejected.

Assuming a single universe of D's for all men, the standard error of the mean was computed to be 0.078 F. Five of the 14 subjects were more than 3 standard errors away from the grand mean (almost 36 per cent instead of the theoretical 0.3 per cent). In fact, 9 of the 14 were more than 2 standard errors away from the grand mean (64 per cent instead of the theoretical 4.5 per cent). The L_1 test for homoscedasticity gave an L_1 value of 0.700, with a probability of less than 0.01. Two extreme items were eliminated, but the probability remained below 0.01. It may be concluded that there is no single morning D(i) applicable to all men, nor is there any single "normal range" of individual morning D's applicable to all men.

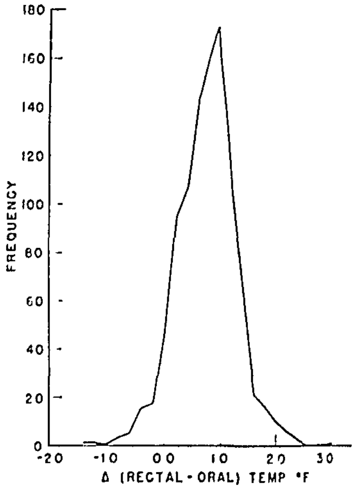

Fig 4.—Distribution of the differences between rectal and oral temperatures of female subjects.

The non-normality of these distributions of D is of great import If there really were a single constant difference between rectal and oral temperatures for all subjects, the distribution of D would, theoretically, be normally distributed. Since the hypothesis of normality had to be rejected it was likely that there was no single constant D for all levels of temperature but that D was correlated in some way with the level of rectal temperature. There was, of course, the possibility that D was a constant value for each subject, but *further analysis casts doubt on this hypothesis.* As a rough test of independence between level of temperature and D, the range in T of each subject was correlated with the range in D. If D were really independent of the level of rectal temperature, there should have been no significant correlation between these two ranges, i. e., the variability in D should be independent of the variability in T.

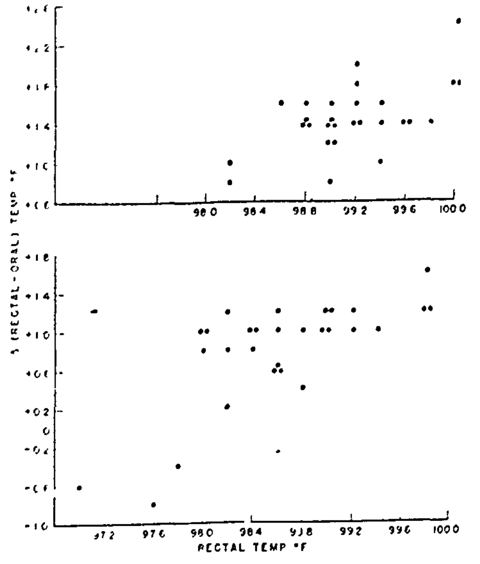

Fig 5.—Scatter diagrams illustrating the relations between rectal temperatures and the differences between rectal and oral temperatures. The data for the upper graph were obtained from a male subject and the lower from a female

There were 14 pairs of ranges for men. When plotted in a scatter diagram, there appeared to be a direct, linear relation-

---

15. In fitting a theoretical normal curve to an actual distribution, the mean, standard deviation and total frequency of the actual distribution were equated with those of a theoretical normal curve and theoretical frequencies were found by the method of areas. The goodness of fit of the theoretical to the actual distribution was tested by computing chi-square and finding the probability of chi-square. The probability of chi-square is the probability of getting a fit as bad as or worse than the one observed if chance were the only factor operating and if the actual distribution were really a random sample from a normal universe. Conventionally, the hypothesis of normality is accepted if this probability is greater than 0.05

16. The L_1 test is based on the relationship between the geometric mean and the arithmetic mean of a series of sample variances. The closer the ratio is to 1, the closer the individual variances are to each other. It is conventional to reject the hypothesis of homoscedasticity (i. e, identical population variances) if the probability obtained from the L_1 table is less than 0.05

ship between the two. Analysis, however, showed no significant correlation. This was due to the presence of a single extreme item. When the one item was eliminated, the correlation was significant at close to the 0.001 level of significance. (The coefficient of linear correlation was +0.76, with a standard error of 0.19; "t" equalled 4.0, with 11 degrees of freedom). For the 34 pairs of ranges for women, the correlation was significant at the 0.001 level of significance. (The coefficient of linear correlation was +0.64, with a standard error of 0.14; "t" equalled 4.6, with 32 degrees of freedom). It would be reasonable to conclude that there was real correlation between D and level of rectal temperature.

Examination of the scatter diagrams of rectal temperatures and corresponding D's by subjects showed a common pattern similar to the ones in figure 5. There appears to be a central range of temperatures within which D remains fairly constant. This constant value was not the same for all subjects, nor was the range of constancy the same for all; at lower temperatures, D decreases and may even become negative (i. e., oral temperature higher than rectal); at higher temperatures, D shows evidence of increasing (fig. 6).

COMMENT

What is normal body temperature? This is by no means an academic question. Physicians are too frequently confronted by a patient complaining of being feverish and yet having a temperature not above "accepted normal" standards. Or on occasion, a patient has vague indeterminate symptoms with nothing more positive than a "low grade fever." What is the relationship between the condition in such a patient and his "normal" body temperature?

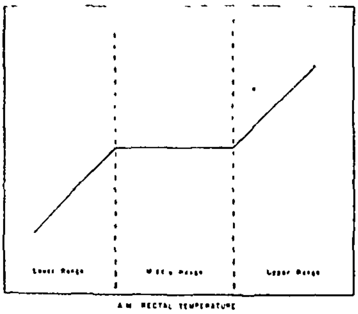

Fig. 6.—A schematic diagram showing the possible relations between absolute levels of rectal temperature and the rectal temperature and the rectal-oral temperature difference.

It is obvious that a part of the difficulty associated with measurements of body temperature lies in a failure to appreciate that "normal" values for body temperature are merely vague statements of someone's average and that a range of values is more significant. Worship of the thermometer with its arrow pointing to a fixed value is definitely harmful. The thermometer can be of greater value if there is an understanding of normal temperature variability and an appreciation of the fact that the shift of body temperature away from or back toward the normal range for the individual patient, rather than a single absolute value, is significant.

The grand mean of rectal temperatures and difference between rectal and oral temperatures and the sigma of the distribution of combined readings reported herein are certainly useful for "gross" evaluation of abnormal temperature. Small deviations from the grand mean, i. e., less than 3 sigma, would give little indication that the subject had an abnormal temperature unless his mean and sigma were known. The importance of individual variation must be recognized and appreciated in order to give meaning to any observation of body temperature.

Almost everyone considers the oral temperature to be a measure of the body temperature of adults. However, despite the ready availability of the oral cavity, the measurement of oral temperature is susceptible, in ordinary practice, to many errors. DuBois[17] has indicated the serious problems associated with this determination. If these variables are controlled and satisfactory oral values are obtained, can they be employed to predict rectal temperatures? Renbourn and Bonsall[6] have reported a positive and significant correlation between rectal and oral temperatures. This has not been confirmed by other investigators,[18] whose results indicated a low degree of predictability of oral from rectal measurements and vice versa. However, the results presented and the scatter diagrams in figure 5 and the schematic diagram in figure 6 suggest that there is correlation between them. The difference between these two measurements is not, however, a fixed quantity, i. e., the regression equation would not be of the form rectal temperature equals oral temperature plus a constant (R=O+C) but would be much more complex.

The present data require considerable extension to confirm the possible correlations that have been suggested (fig. 6). Some information has been presented by Shelley and Horvath[19] at the upper levels of rectal temperature, which agree with the suggestion that the differences between oral and rectal values would be greater at those points. The mean difference observed by these investigators was 1.2 F., in contrast with an approximate mean difference of 0.8 F. observed in this study. However, such generalizations must be viewed with caution, since in the same subject and among subjects variations are large and would prohibit any such simplification of fact.

SUMMARY

The mean morning rectal temperature of women was not only higher but variability in the mean values was greater than for men over a comparable period of 29 consecutive days. Both men and women had a significantly higher mean evening rectal than mean morning rectal temperature. There is no single "normal" temperature value for all men. Neither is there a single "normal range" of temperature for all men. These statements are equally true with respect to the differences between rectal and oral temperatures. In any specific person there was no single constant rectal-oral difference over his range of body temperature. A correlation of this difference with the absolute level of rectal temperature was noted, but the precise nature of this relation was not fully analyzed.

REPORT OF THE COUNCIL

The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.

HOWARD A. CARTER, *Secretary.*

MEDCOTRONIC STIMULATOR, MODEL 50, ACCEPTED

Manufacturer: Medco Products Company, 3603 East Admiral Place, Tulsa 12, Okla.

The Medcotronic Stimulator, Model 50, is a generator of electric currents for the stimulation of human muscles. The three types of current produced are described by the firm as: 1. Pulse: Provides a twitch contraction of normally innervated muscle. The "pulses" of current can be varied from approximately 1 to 7 per second at a setting of 1,000 cycles, or from 2 to 14 per second at a setting of 2,000 cycles. 2. Surge: Provides a graduated muscle contraction. During the "on" period the current gradually builds up to full strength in 2 to 3 seconds. There is a 6 second "off" or rest period. 3. Tetanizing: Provides a constant tetanic contraction of muscle. The currents are the same as "surge" currents, approximately 1,000 or 2,000 cycles per second superimposed on a ½ rectified 60 cycle sine wave, but in this case they are not interrupted. The above descriptive terms are not those in general use, but the Council recognizes that the nomenclature in electrotherapy is not uniform. The Council on Physical Medicine and Rehabilitation voted to include the Medcotronic Stimulator, Model 50, in its list of accepted devices.

ACTION OF LIPOTROPIC SUBSTANCES IN LIVER DISEASE AS MEASURED BY RADIOACTIVE PHOSPHORUS

The liver is an organ of many functions. Tests have been designed to measure alterations in function in hepatic disease, but these tests are often relatively crude and do not detect small decreases in activity. No test has been devised which can assay the functional capacity of the liver for some activities which are known to exist. Until recently, for example, no means had been developed to measure new phospholipids entering the blood, though it has been known for some time that the blood phospholipids are derived almost entirely from those formed in the liver.[1] The synthesis of phospholipids is a function of primary importance to the body and cannot be measured by a chemical method. The application of an isotopic technic to this problem makes possible the accurate measurement of the excess, over their normal breakdown and catabolism, of newly synthesized substances which incorporate the labeled atoms of phosphorus (P^{32}) into the molecule.[2]

Stress of various types is known to damage the liver. The harmful action of poisons, such as carbon tetrachloride and heavy metals, has long been known. More recently, infections in distant parts of the body—as well as parasitization of liver cells themselves—has been recognized to decrease liver function.[3] The association of alcoholism with liver damage has been discussed for many years. Apparently the damage is not the result of alcoholic intoxication per se, since not all persons with a high intake of alcohol exhibit liver damage. It is likely that a deficiency of some substances, induced by the restriction of diet which often accompanies alcoholism, is at fault. The question is, What substances and what degree of deficiency? Liver cells damaged in this fashion tend to accumulate neutral fat and fatty acids which can be detected by histologic staining technics that permit visualization of lipids. The presence of fat appears to hinder the regeneration of liver cells—a process which usually follows injury rapidly and often proceeds to an amazing extent.

Attempts have been made to decrease the lipids deposited in the liver by restricting the intake of fat and by forcing the ingestion of a high carbohydrate diet, supplemented with infusions of dextrose. These efforts resulted in some clinical improvement. A high protein diet has proved to be much more effective in the treatment of cirrhosis. Vitamins of the B complex are associated with proteins, chiefly nitrogen-containing compounds—such as the base choline—and amino acids. The sulfur-containing amino acid, methionine, apparently is necessary for the regeneration of cells; it also furnishes methyl groups and may serve as a precursor for choline. Choline, which acts as a lipotropic substance, apparently is necessary for the mobilization of neutral fat through the formation of choline-containing phospholipids[4]; non-choline-containing phospholipids are also formed simultaneously but do not mobilize fat. The introduction of competitors for methyl groups (methyl acceptors) may decrease phospholipid synthesis in the liver and thus enhance the production of fatty liver. The action of choline or of methionine in effectively mobilizing lipids can be demonstrated by serial liver aspiration biopsies. Studies of the liver by this anatomic technic demonstrate that the addition of lipotropic substances in the treatment of liver disease does not effect improvement in all instances. This failure raises the question of whether a deficiency of lipotropic substances may exist in human beings and whether correction of the deficiency can be correlated with an increase in phospholipid formation, as well as disappearance of fat from liver cells.

The application of the new isotopic technic has demonstrated that choline deficiency does occur in man.[5] Biologic technics which utilize the rate of growth of bacteria as an indicator measure the excretion of choline in the urine after the body is saturated with the substance, but they do not measure the utilization of the lipotropic material.

The normal range of phospholipid synthesis has now been determined in man.[6] Considerable individual variation has been observed, but in a given person the rate of synthesis or turnover remains rather constant over a period of months. The synthesis of new phospholipids cannot be increased in the normal person by the administration of choline or methionine.

In patients with chronic hepatitis (Laennec's or atrophic cirrhosis) lipotropic deficiencies can often be demonstrated at the start of therapy.[7] In an acute exacerbation the administration of a large dose of choline or methionine will cause an increase in synthesis of phospholipids. Once the deficiency has been overcome, the rate of phospholipid turnover remains rather constant for that individual, as long as the diet remains adequate and physiologic stress (alcohol intake and activity) is unchanged. In the interpretation of results in a disease which has so many variables, each subject must serve as his own control. Experiments by these technics over a period of months in patients with cirrhosis have shown that in this group phospholipid synthesis is in the low normal range. Occasionally, an old, small, scarred liver of chronic cirrhosis will show improvement in other functions—such as pigment metabolism or protein synthesis—without a change in rate of phospholipid synthesis or detectable anatomic change. Phospholipid synthesis must be a primitive function and one of the last to disappear in liver decompensation.

In patients with acute virus hepatitis no lipotropic deficiency has been demonstrated and no alteration in the rate of phospholipid synthesis has been detected by the addition of methionine or choline to a treatment regimen.[8] No good evidence exists that a reduction in protein intake is an etiologic factor in the disease or that stores of protein and lipotropic substances are rapidly depleted by the infection and the temporarily reduced food intake resulting from nausea and anorexia. The liver in virus hepatitis is usually enlarged, and the anatomic changes can be readily followed by serial aspiration biopsies. Jaundice, in the presence of normal phospholipid turnover, indicates that all functions of the liver are not damaged simultaneously in equal degree. Anatomic as well as physiologic technics are necessary to assay the type and extent of liver damage.

These important new studies may be immediately applicable to improvement in treatment of human disease. A deficiency in lipotropic substances apparently sets the stage for accumulation of fat in the liver. But how long an interval of time on a protein deficient diet is required in the absence of stress to produce a lipotropic deficiency? In rats the time is as short as five days, but no data are yet available for man. The rapid decrease in function and increasing seriousness of the clinical condition of those with cirrhosis who go on week-end drinking sprees suggests that the time may be shorter than now suspected. Since stress (anesthesia, trauma, infection) will induce a decrease in liver function in normal persons, one wonders whether it will prove possible to prevent liver damage by prophylactic administration of lipotropic and other substances when stress can be anticipated.

It may be possible to improve further the current regimen of treatment of chronic hepatitis by reducing the work now required of the liver. Energy is required to metabolize amino acids and to form urea from the nitrogen of the molecules. Experiments by the same group of investigators have indicated that in animals, at least, the stress of radiation from isotopic phosphorus can be reduced in toxicity and the survival time increased by reduction of the protein content of the diet.[9] This observation suggests the interesting possibility that a decrease in the current high protein intake of 140 to 150 Gm. per day might be feasible without a loss in efficacy of the treatment regimen, if lipotropic substances are furnished to the body. A high intake of vitamins, especially of the B complex and the unidentified trace substances which are present in crude liver, will probably have to be provided, but critically ill patients now being lost may be saved.

ALVEOLAR CELL TUMOR OF THE LUNG

Accumulated evidence within recent years has established that carcinoma of the lung arises in a bronchus; it is therefore referred to as bronchogenic carcinoma. A new entity, alveolar cell tumor of the lung, has recently attracted considerable interest because of its apparent origin from cells lining pulmonary alveoli, its multicentric origin and its striking morphologic similarity to "jagziekte" of sheep. The word "jag" is derived from the Dutch "jagt," which means drive, and "ziekte," which means sickness; the combination of the two is meant to indicate that the initial symptoms become first noticeable when the animals are driven for some distance. In the United States the disease is known as "Montana chronic progressive pneumonia." This pulmonary adenomatosis has also been observed in horses and in guinea pigs. Alveolar cell tumors in human beings were variously described as "primary multiple carcinoma," "multiple nodular carcinoma," "alveolar cell carcinoma" and, more recently, "alveolar cell tumor." This neoplasm does not resemble any other pulmonary growth. The tumor presents itself in two forms, as a multiple nodular, or miliary, type and a diffuse, or pneumonic, type.

Malassez in 1876 gave the first description of a multiple nodular alveolar cell tumor. The literature now contains 52 cases, in 49 of which the disease was diagnosed post mortem, while in only 3 was the diagnosis made from a histologic study of the surgically removed specimen.

[8] Cornatzer, W. E., and Cayer, D.: Phospholipid Synthesis in Patients with Cirrhosis and Infectious Hepatitis: The Effects of Choline and Methionine as Measured by Radioactive Phosphorus, South. M. J. 43:212-217 (March) 1950.

[9] Cornatzer, W. E.; Harrell, G. T., Jr.; Cayer, D., and Artom, C.: Subacute Toxicity of Radioactive Phosphorus as Related to the Composition of the Diet, Proc. Soc. Exper. Biol. & Med. **73**: 492-495 (March) 1950.

Wood and Pierson [1] reported the first case in which the disease was diagnosed ante mortem. The removed lower lobe of the right lung in their patient grossly resembled noncaseating disseminated miliary tuberculosis. Microscopically the most prominent feature was the multicentricity of hyperplastic columnar epithelial cells lining the alveolar walls, showing all degrees of proliferation from simple lining to papillary and cystadenomatous arrangements. There was striking preservation of alveolar stroma devoid of epithelial invasion. Only hyperplastic alveolar changes were found, none being present in the bronchi. Drymalski and his co-workers [2] reported three cases, one of which is the second recorded surgical specimen of this condition. Delarue and Graham [3] reported the third patient treated surgically. These authors were likewise impressed with the multicentric nature of the lesion and felt that the term "alveolar cell carcinoma" properly described the condition. Ikeda [4] reported three cases with postmortem diagnosis. Laipply and Fisher [5] described two cases of pulmonary alveolar cell tumor of the lung. One of these was a case of a diffuse alveolar cell adenomatosis with two foci of cancerous change; the second was an instance of a bilateral multiple nodular alveolar cell carcinoma. In both instances the clinical signs and symptoms were those of chronic pulmonary disease with failure of the right side of the heart. These authors emphasize the striking similarity of morphologic features between alveolar cell tumors of man and similar lesions in sheep, mice, horses and guinea pigs.

Good and his co-workers [6] have observed eight patients with alveolar cell tumor of the lung at the Mayo Clinic since 1943. These patients were treated surgically. They found four additional cases in their files in which the diagnosis was made at necropsy. The most valuable single aid in the diagnosis of the tumor, the authors found, was the cytologic examination of sputum or of bronchial secretions. Operation, in their opinion, is the only effective treatment. It is indicated whenever the lesion is localized in one lung or one lobe of the lung.

The problems with respect to genesis of the tumor pertain to (1) existence or persistence of epithelial cells in the lining of alveolar spaces, (2) similarity to "jagziekte" or pulmonary adenomatosis in animals and (3) etiology. The presence of lining cells in the pulmonary alveoli has been the subject of many controversies. Human embryologic studies suggest that the epithelial lining of the terminal vesicles begins to disappear about the end of the fifth month of fetal life. The epithelium of the respiratory tract in the adult appears to terminate more or less abruptly at the beginning of the alveolar ducts. Neubuerger and Geever [7] point out in their review that three views exist at present: 1. The alveoli in the adult have a continuous epithelial lining. 2. The alveoli have a discontinuous epithelial lining in the form of isolated cells or nests in the niches between the capillaries. 3. No true lining exists, but the capillaries are contained in a ground substance with occasional "septal cells," probably of mesenchymal origin. It is agreed, however, that under certain pathologic conditions the alveoli have a definite lining. Arkin and Wagner, Fried and Geschickter objected that there can be no carcinoma primarily in the alveoli since they have no epithelial lining. Neubuerger considered that the alveolar lining as seen under pathologic conditions develops from mesenchymal septal cells and that a continuous developmental relation exists between the occasional production of lining in inflammatory conditions, on the one hand, and the alveolar cell tumor, on the other. He refers to a study by Jane Oppenheimer [8] concerning the specificity of the germ layers. On the basis of important contributions in this field she has concluded that the doctrine of the absolute specificity of the germ layers as enunciated in the last century must be abandoned. The germ layers are probably capable under certain conditions of undergoing variations. Neubuerger concludes that the possibility of mesenchymal cells giving rise to tumor with epithelial-like cellular elements cannot at present be rejected.

ERYTHEMA NODOSUM

Erythema nodosum is in most cases so typical that diagnosis does not present any difficulties, but there are questionable borderline cases. The concept that it is associated with tuberculosis now seems prevalent. Holmdahl [1] concludes that the primary infections seem to be combined with erythema nodosum to about the same extent during the various periods of childhood.

with the exception of the first years of life. On comparison of "invertors" with cases of primary tuberculosis accompanied by erythema nodosum, the risk of pleurisy and postprimary pulmonary tuberculosis seems to be greater among the erythema nodosum cases. If cases of hilar adenitis with and without erythema nodosum are compared, it is not possible to demonstrate a significant difference. It seems that primary tuberculosis gives similar symptoms in children and in adults but with advancing age gives increasingly less pronounced primary changes. Healing is more rapid in older children, while the risk of the development of meningitis seems to be higher in cases with extensive hilar adenitis changes. Invertors with primary changes run a greater risk of contracting pleurisy and pulmonary tuberculosis than invertors without primary changes. There is considerable risk of the development of postprimary tuberculosis in adults as well as children, but the risk of meningitis seems to decrease with advancing age. The opposite seems to apply to postprimary pulmonary tuberculosis. It is clearly apparent that the risk of development of pulmonary tuberculosis is greater for invertors in adulthood than in earlier life. This is also the case in primary tuberculosis associated with erythema nodosum. Exudative pleurisy, except for first years of life, is a common complication in childhood as well as in adult life. The risk of incurring pleurisy following primary infection is somewhat greater in adults than it is in children. Holmdahl followed 657 patients with primary tuberculosis with erythema nodosum from birth to 16 years and found that 52.2 per cent acquired their primary infection between birth and 7 years of age. Phlyctenulosis occurred in 6.5 per cent of cases of erythema nodosum. The mortality from postprimary tuberculosis was greatest among those cases of primary tuberculosis which were the result of intrafamilial infection. In 537, unquestionable primary tuberculosis was present. Hilar changes were established in 94.7 per cent and parenchymal pulmonary changes in 59.8 per cent. Thirty-two patients (4.9 per cent) died of tuberculosis, and in 147 (22.4 per cent) one or several forms of postprimary tuberculosis developed. There were 17 cases of tuberculous meningitis, 1 case of miliary tuberculosis without meningitis, 83 cases of exudative pleurisy, 50 cases with certain and 17 cases with doubtful postprimary pulmonary tuberculosis. All of the patients in whom tuberculin tests were completed were still tuberculin positive after a mean period of 14.5 years. There were 14 deaths from causes other than tuberculosis, and tuberculosis was not contributory to these deaths. The observed prognosis was less favorable in those cases of primary tuberculosis with erythema nodosum in which primary tuberculous changes were demonstrable and in which the course of the primary changes or the rise in sedimentation rate was protracted.

Stimulated to an interest in erythema nodosum by Arvid Wallgren, Rollof[2] points out that the various theories of etiology of erythema nodosum are not in agreement. Some consider it a disease caused by a specific virus, while others consider it an accidental phenomenon of allergic nature in different diseases. The occurrence of erythema nodosum in association with various drugs may prove helpful, and Rollof notes the significance of sulfathiazole in children mainly with reference to primary tuberculosis. Accordingly 706 patients were studied: 231 were tuberculous and 475 were nontuberculous. Of the latter, 98 were BCG vaccinated and tuberculin positive and the remainder were tuberculin negative. All the nontuberculous patients had had some other infection for which they had been treated with sulfathiazole. Erythema nodosum following sulfathiazole therapy occurred in 129 cases, of which 105 (81.4 per cent) were tuberculous and 24 (18.6 per cent) nontuberculous. Among tuberculous cases, sulfathiazole erythema nodosum occurred in 45.5 per cent; among nontuberculous it occurred in 5.1 per cent. The difference is considered statistically significant. The incidence of erythema nodosum in cases of primary tuberculosis was higher when sulfathiazole was administered, either therapeutically or experimentally. The frequency of erythema nodosum following sulfathiazole therapy is inversely proportional to the duration of the tuberculous process. The more recent the process, the higher the frequency. It could not be concluded with certainty that there was a relation between the development of erythema nodosum following sulfathiazole therapy and either the activity of the tuberculous process or the presence of "multiple infection," such as beta-hemolytic streptococci in the throat. There was no evidence that erythema nodosum resulted from hypersensitivity to sulfathiazole. Erythema nodosum can develop in association with treatment with other sulfonamides, but frequency is low compared with that associated with sulfathiazole therapy. No difference was observed between the lesions of spontaneous erythema nodosum and those of erythema nodosum following sulfathiazole therapy, although in the latter the lesions clear up rapidly when the drug is discontinued without passing the color phases of the spontaneous type. Perhaps spontaneous erythema nodosum and erythema nodosum following sulfathiazole therapy is a manifestation of an allergic phenomenon caused by some kind of infection, the sulfathiazole acting the part of a provocative fact, but no evidence is presented to explain its action.

THE PRESIDENT'S PAGE

A NEW YEAR'S MESSAGE

Although as this is being written I am hoping that all of you will have a joyful and blessed Christmas, the publication date of this issue permits me only to extend to you my sincere best wishes for a happy and very successful New Year.

It is going to be an eventful year . . . a year of momentous importance to the medical profession and to the world. Grave international problems must be faced and solved. Every American must devote himself with renewed vigor and earnestness to whatever his task may be.

It is incumbent on the medical profession as a whole, and doctors individually, to be especially alert, especially active. Our professional position is not, as we have long since learned, one of isolation. It is integrally and indivisibly a part of the structure of American public life. The medical profession now has the public confidence in higher degree than ever before, because it went to the people, told the truth and revealed state socialism for the universal danger it is. We can be proud of that, but we must live up to it.

The coming year will be one of new regulations, new restrictions; of growing economic problems and international crises. We will be living under government controls necessary to the defense of our liberties—and we probably will be living under those controls for some years to come. All the more important, then, that we think straight and talk straight, and that we have a sound understanding of world and national affairs

The progress of American medicine in 1951 will be great, indeed, if we continue the historic advances made during this past year. I think I know how the ancient god Janus felt, looking forward and backward at the same time, because I can see so much in the past that portends so much in the future.

One weak sector in medicine's front line, unfortunately, has been organized labor. Not the men and women themselves, but the officials who rule the unions. Union men and women have expressed themselves in no uncertain terms as being opposed to communism and the deadening hand of socialism. They defied their leaders in last November's election and supported those candidates whom their leaders were most viciously opposing. Among the rank and file are strong allies for medicine, and we must make it one of our 1951 resolutions that their friendship shall not be neglected.

But splendid as this grass roots support is, I find even more gratifying the courageous and challenging statement by William L. Hutcheson, General President, United Brotherhood of Carpenters and Joiners of America, that he and his powerful, highly respected union stand shoulder to shoulder with the doctors of America in opposing socialized medicine and all forms of state socialism. Mr. Hutcheson's action will be a landmark in our continuing campaign against the evils of governmental control of medical care, and it opens to all of us a whole new field of work on the local level. It is a cheering note, and a challenge, for 1951.

Another milestone was passed in 1950. When the Board of Trustees voted unanimously to appropriate $500,000 as the nucleus of a private fund to provide financial aid for medical schools, it at once threw a stinging rebuke at the critics of American medicine and set the keynote for the coming year.

The appropriation is solid, material proof that the medical profession is not just fighting against something, but is, and has been, doing positive things. The advancement of medical education is not a new activity of the American Medical Association, of course. Annually the Association spends a quarter of a million dollars for that purpose through its Council on Medical Education and Hospitals. But the new fund will provide a vehicle for private financing of our medical schools, and can end forever the arguments that federal funds are their only salvation. Here again is a cheering note and a challenge. We must extend to all of our communities the drive for contributions from private sources.

Yes, the past year has been a great awakening, a great reaffirmation of faith in fundamental American liberties. It is my prayer that we all may be given the strength and the courage and the wisdom to do our parts as good Americans and to keep ever alive that internal fire that is the last hope of all free men, the last beacon of liberty in a darkening world.

Elmer L. Henderson, M.D.
Louisville, Ky.

WASHINGTON NEWS

(From the Washington Office of the American Medical Association)

Local Health Units

The legislative situation regarding federal aid to local public health units has undergone significant change One bill passed the Senate in 1949 (S 522), and another (H R 5865) was tabled by the House Rules Committee early this month when the chairman of the National Security Resources Board failed to appear to testify for it The American Medical Association, while consistently approving the objective, opposed this legislation on the ground that it gave the federal administrator too much authority and that the definition of "public health services" was not sufficiently restrictive Now, however, a new bill has been introduced which emphasizes the civil defense aspects of local public health units and to some extent corrects features to which the Association objected

The revised legislation was introduced by Representative Percy Priest (Democrat, Tennessee), a member of the medically important House Interstate and Foreign Commerce Committee and chairman of its Health Subcommittee Mr Priest's bill (H R 9914) is designed to "provide basic full time public health services as rapidly as practicable in all areas of the nation and particularly in national defense areas, and in the training of all types of personnel for local public health unit work" Programs would be assisted by federal funds but subject to supervision by the state health authority or department of health The Surgeon General of the United States Public Health Service would set certain minimum standards of professional personnel and services, which state plans would have to meet before approval for participation Before issuing these regulations, the Surgeon General would be expected to consult with state health authorities, and he would be required to consult with them before making any later revisions The state would have to present evidence that it would extend coverage "as soon as practicable" to all national defense areas, as defined by the Surgeon General after consultation with other federal officials concerned with civil defense Furthermore, the local units would have to be sound financially, each would have to service an area with sufficient population and resources to assure continued financial support Other restrictions Funds allocated to states for public health units would have to be used for such units and for no other purpose, and other federal grants to states could not be turned over to health units and counted as a state contribution Appropriations for continuation of the program would not be authorized after the present national emergency is terminated

Under H R 9914, public health services are restricted to health education and information, laboratory services, vital statistics, communicable disease control environmental sanitation, maternal and child health and training of personnel for local public health work or other aspects of preventive medicine Public health units would be specifically forbidden to engage in medical or dental treatment except as necessary for communicable disease control or to meet epidemic or other emergency situations

Like earlier bills on the subject, H R 9914 provides for federal money to be distributed to local public health units through state health authorities applying a formula which would give poorer states proportionately more federal money However, federal contributions could not exceed $1 per capita in any local unit, regardless of the amount per capita contributed by state and local sources Under the formula, federal contributions would be less than 50 cents per capita only in states where the state's per capita income exceeded the average national per capita income

A week after Mr Priest introduced his new bill, the Federal Security Agency released a new pamphlet, "Your Best Buy," which "tells something of the services, staff and financing needed for a satisfactory local health program and explains how investment by a community in such a program helps buy health protection for its citizens" In popular language it explains how, for $1 50 per person from local and federal funds a community may maintain the basic public health services

Blood Collection by Red Cross

Between now and July 1, the Red Cross estimates that it will have to arrange for the full time or part time services of at least 50 physicians to supervise blood collecting centers and handle mobile units An indication of the scope of the Red Cross blood program came when the Defense Department announced that it was turning over $3,000,000 to the Red Cross immediately and that an additional $9,000,000 had been set aside for future financing of the program Money will be expended solely for the new plasma stockpiling program and for collection and handling of whole blood for overseas shipment to the armed forces Defense Secretary Marshall pointed out that all costs incident to collection and shipment of blood for the armed forces from the beginning of hostilities in Korea to Dec 1 1950, have been paid by the Red Cross but that now "the new and greatly expanded program requires additional funds beyond the planned budgetary estimates of the Red Cross' In addition to servicing the armed forces, the Red Cross blood program will have to supply large quantities of stable blood derivatives for civil defense stockpiling, pending the possible approval and production of substitutes It is understood that the Red Cross plans to set up 20 additional centers, similar to those in use in World War II An effort will be made to enlist the help of physicians in the local communities on a part time basis, for which they may be compensated If this is not successful, the Red Cross will ask the military services to assign physicians to it, following the procedure resorted to at some stages in the last war

Note to Doctors Returning to Military Service

At this writing the House has passed and the Senate is expected to pass a bill (H R 9911) providing $10,000 term National Service Life Insurance without cost to servicemen However, $10,000 is the limit—your beneficiary would not be eligible to receive any NSLI in excess of this amount, even though you may have kept in effect in another form all or part of the $10,000 optional NSLI available during your previous service Regulations undoubtedly will be prepared to simplify the procedure for holding in abeyance your present NSLI policy while you are in service and covered by the new $10 000 policy

Scientific Manpower Advisory Committee

The National Security Resources Board's Scientific Manpower Advisory Committee is ready to function, with appointment of 11 members The chairman is Charles A Thomas, executive vice president of Mansanto Chemical Co Members are Chester I Barnard, president of the Rockefeller Foundation and General Education Board, New York J Douglas Brown, dean of the faculty, Princeton University Vannevar Bush, president of Carnegie Institution, Washington, D C Ralph Connor, vice president of Rohm and Haas Company, Philadelphia Lee DuBridge, president of California Institute of Technology, Pasadena, Calif , Everette Lee De Golyer, oil geologist engineer and consultant, Dallas, Texas, Jacob Dever, Major General, U S Army (retired), Washington, Gordon Gray, president of University of North Carolina Chapel Hill, Ben Moreell, board chairman and president of Jones and Laughlin Steel Corporation, Pittsburgh, J C Warner, president of the Carnegie Institute of Technology, Pittsburgh, and Harry A Winne, vice president of General Electric Co, Schenectady N Y

The Committee will make recommendations to guide NSRB chairman W. Stuart Symington in formulating policy "regarding the maximum contribution to national defense from the nation's scientists, engineers and other technical personnel." In general it will not be concerned with the medical profession, where the authority is Dr. Howard Rusk's NSRB Advisory Committee. However, the understanding now is that the scientific manpower committee will have jurisdiction over certain classifications of scientists and technicians employed by or associated with medical schools and laboratories.

Field Tests of Equipment

The Army is making final on-the-spot field tests of improved medical equipment and drugs in Korea. Two Army physicians and a civilian consultant are in Korea checking the effectiveness of several new types of equipment with a view to general standardization for use throughout the Army. Lieut. Col. Edwin J. Pulaski and Major Curtis P. Artz of Brooke Army Medical Center, Fort Sam Houston, Texas, and Dr. Henry K. Beecher, consultant in anesthesia, Massachusetts General Hospital, Boston, will spend about six weeks in Korea testing the new devices and drug combinations.

Here are some of the projects they will evaluate:

1. Injection devices that may be discarded after use. One is a sterile needle attached by a rubber tube to a glass container partially filled with the drug. Part of the container is occupied by helium gas under pressure. Once the seal is broken and the drug injected, the glass can be thrown away. The other disposable needle is a syrette, the needle of which is attached to a tube of morphine or morphine substitute. A plastic top covering the needle is unscrewed and a shield inserted to break open the top of the tube, releasing the fluid.
2. A stainless steel bone pin replacing a cast in cases of a broken thigh bone. The pin is inserted in the end of the broken bone, through the marrow cavity, allowing the patient to become ambulatory sooner and permitting bone structure to form more rapidly.
3. Portable x-ray machines and accessories. Since World War II these have become lighter in weight and more flexible, making possible earlier determination of the extent of injury.
4. Portable, lightweight anesthesia machines for field service.
5. Two oversized wound or burn dressings for first aid use that can be left on the patient for as long as 14 days. (Present dressings must be changed every day or two.) Bandages are five times as large as any now in common use.
6. "Gunshot" injections of a combination of drugs. Penicillin and chloramphenicol have been used in combination before, but now streptomycin, aureomycin and terramycin have been added to the one-shot injections. It is known that singly these drugs combat different bacteria to varying degrees. By injection of the drugs in combination, the scope of attack on unknown bacteria is increased. The combination of drugs used depends on the location of the wound.
7. Pituitary adrenocorticotropic hormone (ACTH) used to retard growth of fibrous tissue, particularly in scarring wounds where growth may choke the nerve and interfere with its function. This decrease in scar formation could be of advantage in wounds to the eye, for example, where a small scar may produce blindness.

Chemicals in Foods

Because it wants to continue its investigation, the House Committee on Chemicals in Foods is not making specific recommendation for legislation in its interim report. The report says the committee wants an additional grant and more time to take testimony, particularly from scientists on the West Coast. Also, the plan is to take two full days of testimony from Department of Agriculture experts, who so far have not been heard. If the money is granted, the committee probably will reopen hearings in January. The committee is attempting to learn to what extent humans are affected by continuous absorption of residue from insecticides and pesticides and of chemicals used in the processing of foods. When it has completed its hearings, the committee probably will recommend more rigid federal controls over such substances.

At its last hearing in December, the committee received testimony from Dr. William J. Darby of Vanderbilt University School of Medicine, representing the Council on Foods and Nutrition of the A. M. A. Dr. Darby first discussed the role of the Council, explaining that members are appointed because of their knowledge of nutrition, foods and health, that they serve without pay and that no charge is made for the services of the Council and its staff.

Dr. Darby read to the committee the Council's definition of a wholesome food, and said, "The Council recognizes the important advantage of the proper use of such agricultural aids as pesticides and of certain of the intentional chemical additives. It holds, however, that proper information concerning the toxicological effects and the possibilities of residues in foodstuffs, methods of detection and assay, must be developed before a pesticide which is likely to find its way into foodstuffs is permitted to be marketed." At earlier hearings, Committee counsel had referred to a statement of caution about new chemicals, appearing a year ago in The Journal. Dr. Darby said, "Since the acceptance of this statement (by the Council) progress has been made and those manufacturers of pesticides who supported this work are to be congratulated." However, he warned, "If the findings of this Committee's hearings reveal that adequate controls and safeguards are nonexistent or are not supplied by existing methods of voluntary control, it is recommended that practical measures be evolved which will serve to safeguard the food supply." Dr. Darby did not endorse or propose any specific type of control.

Legislative Notes

Several amendments from the floor proposing appropriations for health services lost out when the House passed H. R. 9920, the supplemental appropriations bill. Eliminated: $75,000,000 to restore to $150,000,000 the 1950-1951 authorization for hospital construction grants, $2,600,000 which would finance the *two new institutes of Arthritis and* Metabolic Diseases and Neurological Diseases and Blindness; and a proposal to assist states in the event of major disasters, including the furnishing of emergency medical services by federal departments. . . . In approving the supplementary military appropriations bill (H. R. 9893), the House Armed Services Committee deleted $800,000 for an Air Force Medical Center but allowed Army Medical Service $8,663,200 for new construction and Navy $478,000 for medical facilities. At this writing, it appears certain the new Federal Civil Defense Administration will be approved by Congress; this legislation has far reaching medical aspects, including regional stockpiling of medical and surgical supplies by the United States and establishment of a network of health offices. . . . Introduced in the House: H. R. Res. 294, to establish a civilian fitness and training program. This would be voluntary and could be established under Veterans Administration, Public Health Service or other agency designated by the President. The bill was referred to the House Interstate and Foreign Commerce Committee, but no action is in sight

Notes

This fiscal year $499,000 will be distributed among the 42 medical schools participating in Institutes of Mental Health programs for undergraduate instruction in psychiatry . . . Public Health Reports vol. 65, no. 49, contains part one of the report of the annual American Public Health Association meeting. . . . The Atomic Energy Commission, University of Rochester Medical School and five Rochester (N. Y.) hospitals are cooperating in a new plan for distribution of radioisotopes for clinical and diagnostic use in that area. AEC explains that "materials will be standardized in the 'hot' laboratory maintained at the Medical School, and doses will be measured, transported to the hospitals, administered to patients and urine collected and counted in accordance with well established technics which will provide adequate safeguards both for patients under treatment and for hospitals and laboratory personnel." . . . FSA has listed state and local vacancies for mental health personnel. Openings for psychiatrists, psychologists, social workers and mental health nurses

ORGANIZATION SECTION

WHAT THE COMMUNITY EXPECTS OF THE DOCTOR

LOUIS B. SELTZER

Cleveland

It has been said that everyone in the world thinks that he could run a railroad or edit a newspaper better than the job is being done. Most people would admit, I think, that they have no idea of how one goes about removing a gallbladder or an appendix. Doctors are usually surrounded by frightened patients and dutiful nurses and I suspect that you are more accustomed to giving advice than to receiving it. I want, therefore, to inject a word of caution at the beginning of these remarks. All of you I am sure know the story of the two psychiatrists who were walking through the lobby of the medical building when a third doctor came by and exclaimed pleasantly, "Good morning." The one psychiatrist turned to the other with a worried look and said, "I wonder what he meant by that."

I trust therefore that you will accept my assurances that my words mean what they plainly say and nothing more. They conceal no hidden meanings. All of this sounds as though I were getting ready to scold you. Actually nothing is further from my purpose. I intend to spend most of my time this evening saying nice things about you, things which I mean from the bottom of my heart. But I shall also discuss some problems with you openly and frankly.

Cleveland, like a lot of other cities in this part of the United States, was buried under an avalanche of snow last week. A business acquaintance of mine called up the owner of a snow plow to find out if he could get the snow cleared out of his driveway. The answer was, "I'll get around to your house tomorrow or the next day, if I can. Today I'm cleaning driveways for doctors only."

In that incident you can find every aspect of the complex relation of the medical man to his community. It indicates that the community accords a special place to the medical man and simultaneously makes special demands on him. It indicates the realization that the community is in desperate need of its medical men. But it also shows that at a time when most members of the community are content to settle down in an easy chair before the fireplace they expect the medical men to plow through six-foot snowdrifts, if necessary, to answer the call of duty.

Your conference this week is devoted to the subject of effective county medical society public relations. I think back to the doctors who were in general practice in my boyhood. Since the medical profession is frequently a hereditary affair, those general practitioners of a generation ago probably included the fathers of many of the men in this room tonight.

I cannot help thinking how they would be puzzled by the subject of your discussion. The family doctor of a generation ago was more than a physician. He was a friend of the family and a tower of strength to it. He practiced psychiatry before that specialty had been invented. The whole family felt better when he walked in the front door. He delivered babies into the world, watched them grow up and get married and delivered their babies in turn. How he would have scratched his head in bewilderment at talk of public relations.

I mention this to call your attention to the fact that the family physician of a generation ago had the world's finest public relations without knowing it. And your goal today should be to seek the same kind of relation with the members of the community that he had. I think I am as well aware as you are of the difficulties involved. We no longer live in the horse-and buggy age. We live in the age of the automobile and the air plane. Life is more complex, cities are larger, and medicine is more complex.

I realize that the x-ray specialist, whose value lies in the fact that he can see things on an x-ray plate more clearly than anyone else, has no time for cultivating the family relations that made the general practitioner of a generation ago the beloved figure that he was. Many branches of modern medicine can be carried on only by specialists with the aid of the complex organization of the modern hospital. Diagnosis often requires complex chemical tests. They are growing more complex as radioactive isotopes become part of the picture. Thus it is that one more specialty, that of public relations, must be added to the other specialties in the field of medicine.

You doctors when called to treat a patient begin by examining him. You make a diagnosis in which you squarely face the facts as they are disclosed to your eye and your diagnostic tests. I think you must face the problem of public relations in the same spirit. You must begin with a diagnosis.

The other day I heard of a southern hospital where a patient was given an injection of penicillin on arrival. If he wasn't cured in 12 hours, they examined him. I don't believe the story. I don't believe that anyone would run a hospital that way. But all too often, public relations are handled that way and it is a mistake. As I have said, public relations must start with a diagnosis. You must start by looking for the answer to a question. And that question is contained in the subject assigned to me for discussion tonight, namely, "What the Community Expects of the Doctor."

The conduct of your public relations program will become a matter of simple operational technics, if you have the right answer to that question. Without benefit of an M.D. degree but on the basis of 35 years' experience in the newspaper business I shall try to make that diagnosis for you. You are privileged, of course, to disagree with me.

The first thing that the public expects is the best that modern medicine has to offer. I shall not take any of your time recounting the achievements of twentieth century medicine. You know that wonderful and magnificient story far better than I do. But side by side with this magnificent advance of medical science has come a new appreciation of health on the part of the public. Never in the history of the world have the people of a nation been so acutely aware of the importance of health.

No newspaper is complete without its syndicated column of medical information. The great metropolitan dailies and the press associations employ highly trained and competent science writers to report on the news of medical meetings and medical achievements. In the terminology of the advertising expert, the American public is health conscious as never before. Being aware of the best in medicine the public naturally wants it. I do not think that anyone will be inclined to regard this as unreasonable. After all, each one of us wants the best possible medical advice and care for ourselves and our families.

Moreover, from the national point of view, health is more than a personal matter. It is a national asset. Our national security depends in large part on it. Health has an economic value. We can express the cost of disease in terms of lost productivity on the farm and in the factory. If we wish, we can state it in terms of dollars and cents as well as in terms of human suffering and misery. Most of the problems of a public relations nature with which you must deal grow out of the fact that there are a considerable number of persons who feel that they are not getting the full benefits of modern medical progress or that the cost of those benefits is too high. This, I think, is your central problem.

I know that the great majority of American doctors, perhaps 99 per cent of them, are sincere, honest, capable practitioners of medicine, motivated by the highest ideals of the profession. And that is why I am going to make the next statement. The public has so high a regard, so sincere a veneration for the honest and competent physician that you cannot afford to protect the doctor who is not faithful to his vows and to the highest ideals of the profession.

I understand that county medical societies everywhere are setting up grievance committees to listen to those patients who think that they have been overcharged or have not received the consideration that they believed was due them. This is a step in the right direction, and it is extremely important that such grievance committees function forcibly and fearlessly.

All too often the medical profession is accused of protecting the incompetent and unscrupulous doctor on the basis of some notion of professional solidarity. It is not in your interest or the interest of the public to protect the doctor who charges exhorbitant fees, who neglects the best interests of his patients, who fails to keep abreast of the tide of medical progress,

---

Editor, *Cleveland Press*.

Read at the Annual Public Relations Conference of the American Medical Association, Dec. 3, 1950, Cleveland.

A few weeks ago I was asked to address the Cleveland Bar Association, and I reminded them that they had this same problem in their profession. As lawyers they are officers of the courts. They have a special duty to preserve the rights of the people and the machinery of democracy. They must be zealous in keeping their own house clean. The same thing applies to you. You, too, have special privileges and special obligations. You are the only ones that may prescribe a powerful drug or wield the surgeon's knife. Therefore you must guard the standards of your profession. You must come to grips with the problem of what to do with the small percentage that would turn the practice of medicine into a racket.

I think that the next thing that the public expects the medical profession to do is to recognize that the subject of medical care is not the exclusive domain of the medical profession. It is the primary concern of every citizen. All too often the medical profession leaves the impression that it regards the discussion of a medical problem by a nonmedical speaker or writer as an unwarranted interference with the practice of medicine.

Physicians have entered the field of politics. I am revealing no secret when I say that. I have noted the part the doctors of Florida played in the defeat of Senator Claude Pepper. I want you to know that I approve of doctors taking an interest in politics. I also approve of lawyers and business men and labor leaders taking part in politics. The survival of American democracy requires that everyone take an interest in politics. I also want you to know that I approve wholeheartedly of your opposition to socialized medicine. I want you to know that I shall not be in favor of socialized medicine until the day arrives that I am also in favor of socialized newspapers. I hardly anticipate the arrival of that day.

But you must realize that in entering politics you are laying yourselves open to the kinds of attacks that characterize politics and you must be prepared for it. Also, you must see to it that your entry in politics does not merely turn you into one more pressure group concentrating its attention on the achievement of its own selfish aims. The only excuse for your entry into politics is to protect both yourselves and the public from unwise legislation and political action and further to exert your influence on behalf of measures that are in the interest of the public.

The avoidance of the evils of socialized medicine is a basic necessity. But it is no solution to the many problems that cry out for solution. I shall not attempt to enumerate all of them. Besides, you know them better than I do. One of them is the problem of the financial plight of the nation's medical schools. I am told that the medical schools of the nation will end the year with a deficit of about $10,000,000. If true, this is far from a healthy situation.

There is also the problem of getting into medical schools. As an editor, I am besieged every year with the tales of students who applied for medical schools and were turned down. I know that the number of students in medical schools is larger today than it has been in many years. Nevertheless, I am constantly told of situations that can be interpreted only on the ground that the United States is suffering from a shortage of doctors. These are some of the problems facing the American public, and they are problems that the medical profession must help solve if it does not wish to be branded as one more pressure group in politics.

The public also expects that the medical profession will come down out of its ivory tower. There was a time when all scientists (and editors) dwelled in ivory towers. Most of the editors have come out, but the medical profession has only descended the stairway as far as the doorway. It is time to come out into the sunshine. Perhaps this indictment is too broad. The situation varies from place to place. In some places it is excellent. This is particularly true of the city in which you are now meeting. The attitude of the Cleveland Academy of Medicine and the Western Reserve University School of Medicine has long been a public-spirited one.

The academy, for example, has long had a committee on public information, which has been of the utmost aid to the newspapers in their endeavor to inform the public of medical news and medical progress. More than a decade ago, this committee arranged what in essence was a seminar in popular medicine for the benefit of reporters charged with reporting medical news. The relations between the academy, the Cleveland Hospital Association and the mediums of public information have been governed by a code of practices well known to many of you as the Cleveland code. This code, which has been widely copied in other parts of the United States, sets forth clearly the rules under which hospitals will give out medical news.

No doubt many of you would like to interrupt me at this point to make a speech on what the doctor expects of the newspaper reporter. I am going to make that speech for you by telling you what the newspapers in Cleveland have done. Each of the three Cleveland newspapers has assigned a full time reporter to the writing of medical news. These reporters are well known to the medical profession. They are governed by the same high regard for medical standards that govern the medical profession itself. They enjoy the confidence of the doctors of the town and the members of the medical school faculty.

I want to take this opportunity to salute these hard-working friends of the medical profession whom many of you know: Josephine Robertson of the *Plain Dealer*, Severino P. Severino of the *Cleveland News*, Don Dunham of the *Cleveland Press* and David Dietz of Scripps Howard.

My suggestion to those of you in communities where newspaper relations are not satisfactory is that the officers of your association sit down with the editors of your local newspapers and talk over the situation. It can be straightened out with mutual understanding. Perhaps I have scolded you too much already. If so, let me say in extenuation that the community expects so much of the doctor because it thinks so much of you. You occupy a very special place in the hearts of your patients. You occupy a very special place in the lives of the community. What criticisms I have voiced here are mild compared with the wonderful story of the achievement of American medicine. What I have said here tonight is said in the spirit of friendliness and sincerity, with the hope that it might be useful to you.

I should like to close on this note by ordering the press and medicine closer to each other. More and more American newspapers have realized the thirst for medical knowledge on the part of the people and the need for intelligent interpretation seasoned with good judgment on the part of the press, and more and more are putting coverage of this news into capable hands. Indeed, I think most of you would agree that the medical profession has had much less quarrel with American newspapers of the highest type the past five years than with some of our best-regarded national magazines. There still is one element of this medical reticence to appear in print that your group should dispel. Working with the serious and tragic phases of life around the clock, as doctor do, many of them are, as we say, unable to take it; they don't like to be kidded. Consequently they are afraid of what their chief or the doctor down the hall or at their luncheon club will say when their name appears in the paper. They assume that such kidding is reserved for doctors. It is not. Most lawyers, engineers, school teachers or retailers also get a bit of that when they make the public prints. It is part of our American way. And it is good for all of us. It is just a little antidote against our getting swelled heads because of the publicity.

There has been no instance in Cleveland in more than 20 years of an official case before the ethics committee of the Academy of Medicine concerning this kind of publicity. That probably would be a surprise to many doctors. Some think it unethical per se for their name to appear in print in connection with their profession.

It has been for many years an unfortunate failing of doctors. It is a bit ridiculous today. With our shortage of doctors and our aroused health consciousness, every doctor worth his salt has all the business he can handle and most of the good ones more patients than they should handle, especially with due regard to the health of the doctor.

We are confident that American industry is the most progressive industry in the world, that in our production lines and Yankee know-how is our great strength and our salvation. And so it is. But with all the progress of our industry, it is virtually standing still compared with medicine and its research, striding forward in sevenleague boots to make the lot of man happier, easier and more comfortable, to ease the pains, to soften the tragedies that are life and death.

The American people after all, in one way or another, pay for all this, no matter from what source the immediate sponsoring money comes. And the American people have a right to know what is going on, with only the rights of the patient protected, and the patient always must be protected.

So take the American people into your confidence, tell them and sell them your story. They are eager customers. I mentioned at the outset that you are here to exchange ideas. Sixty-five years ago, a great man lay on his deathbed in France. His last words were "There is nothing in the world as powerful as an idea whose hour has come." The hour of American medicine surely has come. The hour to tell its story is here. Doing that, the American people will stand with you in the inferno of any battle.

GOVERNMENT SERVICES

Veterans Administration

Facsimiles of Veterans Roentgenograms

Facsimiles of roentgenograms for use in the treatment of veterans are being produced by the Veterans Administration through a new mass production process. Now, when a VA clinic or hospital or doctor needs a previously made roentgenogram in the treatment of a veteran, the request will be sent to the VA Philadelphia Records Center, which will make a facsimile; the original will be retained in VA files. The facsimile need not be returned. All roentgenograms, many of which are now held in regional offices and other VA installations, may be consolidated into a single library at the Records Center. Solarization is the basic technic used. The solarization process requires a tremendous increase in exposure over what is ordinarily considered normal. The "overexposure" requires an extremely large volume of light. The color of the exposing light also has an important bearing on the quality of the reproduction. To overcome these obstacles, a printer was designed to meet the special needs of the laboratory. VA said the present production capacity is 80 to 100 facsimiles a day. It can increase this figure to 400 with additional personnel.

Appointment of Consultants

Dr. Brian B. Blades, professor of surgery, George Washington University, has been appointed to the VA's Special Medical Advisory Group, which met in Washington December 4. The following men have been appointed to the Board of Chief Consultants to VA's Chief Medical Director, Dr. Paul B. Magnuson: Dr. Osborne A. Brines, professor of pathology, Wayne University, Detroit; Dr. Herbert L. Mantz, Kansas City Health Department; Dr. Walter O. Klingman, associate professor of neurology, University of Virginia, and Dr. Donald A. Covalt, associate professor of rehabilitation, New York University Institute of Rehabilitation and Physical Medicine.

Personal

Dr. Don E. Nolan, chief of professional services, Veterans Administration Center, Dayton, Ohio, has been named manager of the 325 bed VA hospital under construction at Seattle, which is expected to receive its first patients next April. Dr. Nolan has been employed by VA since 1938. He is also assistant professor of internal medicine, University of Cincinnati Medical School, and a diplomate of the American Board of Internal Medicine.

Dr. Franz J. Kallmann, assistant clinical professor of psychiatry at the New York Psychiatric Institute, spoke at the Veterans Administration Hospital, Northport, Long Island, N. Y., November 6 on "Results of Twin Studies on the Significance of Genetic Factors in Personality Development."

Dr. William W. Fellows, chief, Surgical Service, Aspinwall, Pa., Veterans Administration Hospital, has been appointed as manager of the 1,005 bed hospital under construction at Albany, N. Y. Dr. Fellows, who has been in VA service since 1931, previously spent six years in private practice at Salisbury. He has been certified by the American Board of Surgery and has served as assistant professor of surgery in the University of Pittsburgh Medical School.

Dr. John A. Seaberg has been appointed manager of the Veterans Administration hospital in Minneapolis, culminating 26 years of experience at that hospital. He replaces Dr. Edwin J. Rose, who goes to the central office in Washington, D. C., as assistant director of the Hospital Operations Service.

Public Health Service

Influenza Information Center

The Influenza Information Center will be continued for a third year. The decision to continue the program on the same basis as last year was reached at a meeting of the Advisory Committee to the World Health Organization Influenza Study Program. All laboratories that engaged in the program last year have been invited to participate again, and several others are included for the first time. This year the center will be under the direction of Dr. Dorland J. Davis of the National Microbiological Institute of the National Institutes of Health. Dr. J. T. Culbertson, director of the center for the first two years, has left the Institutes for a position as associate medical director, Medical Division, E. R. Squibb & Sons.

The committee also agreed that it would be important to continue to have rapid information concerning the laboratory diagnosis of any epidemic disease. Accordingly the Regional Laboratories again have been requested to report laboratory findings on other infectious diseases in unusual incidence. The laboratories of the armed forces are collaborating in the program by making their laboratory observations available to the Influenza Information Center.

Following is a list of the special regional laboratories and their directors:

Boston City Hospital, Dr. Maxwell Finland, New England.

New York State Health Department, Albany, Dr. Irving Gordon, New York, New Jersey, Pennsylvania (Eastern), Delaware, Maryland, District of Columbia.

University of Pittsburgh, Dr. Jonas Salk, Pennsylvania (Western), Ohio, West Virginia.

University of Michigan, Ann Arbor, Dr. Thomas Francis, Jr., Michigan, Indiana, Illinois, Wisconsin.

State University of Iowa, Iowa City, Dr. A. P. McKee, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, Kansas, Wyoming, Colorado.

California State Dept. of Health, Berkeley, Dr. E. H. Lennette, Montana, Idaho, Utah, Nevada, Arizona, Washington, Oregon, California.

U. S. Public Health Service Communicable Disease Center Virus Laboratory, Montgomery, Ala., Dr. M. F. Schaeffer, Virginia, Kentucky, North Carolina, South Carolina, Tennessee, Georgia, Alabama, Mississippi, Florida, Louisiana, Arkansas, Oklahoma, Texas, New Mexico, and other state or local health departments which may wish to collaborate.

School of Tropical Medicine, San Juan, Puerto Rico, Dr. E. Perez, West Indies.

University of Toronto, Canada, Dr. C. E. Van Rooyen, Canada.

The listing of regional laboratories remains the same as that of last year (The Journal, March 18, 1950, page 825).

Symposium on Metabolic Disturbances

A symposium on "Metabolic Disturbances During Surgical Care" will be held Friday, January 12, in Bethesda, Md., at the National Institutes of Health of the United States Public Health Service. Leading investigators in the field of experimental surgery will attend. Visitors are invited to participate in the discussion. The symposium will meet in Wilson Hall in the Administration Building at the National Institutes of Health. It is sponsored by the surgery study section of the USPHS. Dr. Frederick A. Coller of the University of Michigan is chairman of the study section. Information about the symposium may be obtained from Dr. John M. Ellis, Executive Secretary, Surgery Study Section, National Institutes of Health, Bethesda 14, Md.

Reserve Officers Association

At the recent Sixth Annual Conference of the Association of Reserve Officers of the U. S. Public Health Service in St. Louis, the following officers were elected for the year 1951: president, Samuel M. Peck, M.D., New York City; vice president, Anna Heisler, Senior Nurses Officer (retired), Washington, D. C.; secretary, James Q. Gant Jr., M.D., Washington, D. C.; treasurer, Julius Fogel, M.D., Washington, D. C., and historian, Ezra B. A. Gratz, D.D.S., Washington, D. C.

MEDICAL NEWS

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Directory of Health and Welfare Agencies.—The Welfare Council of Metropolitan Los Angeles has published its 1950-1952 Directory of Health and Welfare Agencies in Los Angeles County. Containing brief descriptions of 674 nonprofit organizations that serve the health, welfare and recreational needs of the community, the new directory gives a comprehensive countywide coverage of both private and public resources. Included is a functional index that classifies agencies according to the services they render. Copies, which sell for $1.85 plus sales tax, may be secured from the council at 729 South Figueroa Street, Los Angeles 17.

New 70 Million Volt Synchrotron.—Dr. Gail D. Adams of the University of Illinois, Chicago, will join the staff of the University of California Medical School at the end of the year to become an associate physicist on a project involving biologic and medical research with the school's new 70,000,000 electron volt synchrotron. He will be associated with Dr. Robert S. Stone, professor of radiology and director of the project. This instrument eventually will be used for clinical therapy. The building for the synchrotron probably will be completed in February, at which time the machine will be installed. Dr. Adams has been associated since 1941 with Prof. Donald W. Kerst, Sc.D. At Illinois Dr. Adams has been interested since 1942 in radiobiologic research evaluating high energy radiation from the betatron in the treatment of deep-seated cancers.

Establish Blood Vessel Bank.—A blood vessel bank has been established in the department of thoracic surgery of the University of California Medical School, Berkeley-San Francisco, under the supervision of Dr. H. Brodie Stephens, associate clinical professor of surgery and director of the J. J. and Nettie Mack Clinic. The bank will collect and store fresh blood vessel grafts. Surgeons throughout the Bay Area will be able to draw on the bank to the extent that grafts are available. Dr. Stephens has already circularized hospitals requesting that their surgical staffs help in keeping the bank supplied with grafts. The financing of the new bank is made possible by funds derived from the $100,000 endowment presented to the University in 1928 by Mr. and Mrs. George Ross of San Francisco, for the establishment of the J. J. and Nettie Mack Clinic as a memorial to Mrs. Roos' parents.

COLORADO

University Appointments.—Dr. David H. Watkins, Rochester, Minn., has been appointed associate professor of surgery, University of Colorado School of Medicine, Denver, and associate chief of the division of surgery, Denver General Hospital, effective January 1. John R. Cann, Ph.D., has been named assistant professor of biophysics, effective January 1. At present Dr. Cann is a senior research fellow in the Gates and Crellin laboratory of chemistry at California Institute of Technology, Pasadena. He is a former instructor in physical chemistry at Cornell University, New York.

ILLINOIS

County Health Departments.—Three more counties have been added to those which have full time public health services. These are Gallatin, Saline and White counties, which voted on November 7 to establish and maintain a tri-county health department. Voters also approved continuing local health department services in Alexander, Pulaski and Shelby counties. The question of establishing a county health department was also submitted to the people of Lake County. The proposition was defeated. Since the enactment of the county health department law, 27 counties have approved the establishment of full time local health departments. These, together with the full time city and local district health departments, provide public health services for about two thirds of the people of Illinois. At the November 7 election, residents of 16 counties in the state voted favorably on a tax levy to provide funds for the care and treatment of their tuberculosis patients. These counties include Brown, Cass, Clinton, Crawford, Fayette, Ford, Fulton, Grundy, Jackson, Jefferson, Kendall, Lee, Montgomery, Morgan, Pope and Warren. The tuberculosis tax measure failed in Perry and Randolph counties.

Arthritis and Rheumatism Research Funds.—The Illinois Chapter of the Arthritis and Rheumatism Foundation, 69 West Washington Street, Chicago 2, has made the following allocations of funds: Illinois Research and Educational Hospitals, $2,000; Mercy Hospital-Loyola University Clinics, $2,000; La Rabida Jackson Park Sanitarium, $1,500, and the Rheumatic Fever Institute, $1,000. This is in addition to earmarked funds (not accepted in the current fund-raising campaign) of $13,500 already turned over to Wesley Memorial Hospital and $3,500 to Michael Reese Hospital. An additional $21,854.56 has been transmitted to national headquarters of the foundation as the Illinois chapter's share of the over-all research program, and $5,000 has been set aside for a special arthritis fellowship in Illinois. About $1,000 remains from the 1949-1950 funds for emergency allocation purposes.

Chicago

Heart Association Changes Address.—The Chicago Heart Association has moved its executive offices from 203 North Wabash Avenue to 69 West Washington Street, Room 601, Chicago 2. Telephone: Financial 6-4675.

Fenger Lecture.—The fifteenth Christian Fenger Lecture of the Institute of Medicine of Chicago will be held jointly with the Chicago Pathological Society on January 26 at 8:00 p. m. at the Palmer House. Dr. Anton J. Carlson, Frank P. Hixon distinguished service professor of physiology emeritus, University of Chicago, will speak on "Some Medicosocial Problems Created by Modern Medicine."

Committee to Select Head of Anatomy Department.—A committee of five has been appointed to select a new head for the department of anatomy in the University of Illinois College of Medicine. Dr. Eric Oldberg will serve as chairman of the committee with other members, Drs. S. Howard Armstrong Jr., Robert E. Johnson of Urbana, Milan V. Novak and Carl C. Pfeiffer. The present head of the department, Dr. Otto F. Kampmeier, has requested that he be relieved from administrative duties on Sept. 1, 1951, in order to devote time to the completion of several books.

Babies Deaths Caused by Bottle Cleaner.—A coroner's jury in November found that a chemical cleansing agent used to wash nursery bottles caused the death of a newborn baby at Grant Hospital in October when it was accidentally introduced into the milk formula. The toxic chemical in the detergent was boron. Three other babies died at the hospital October 12-14, and several others were stricken but recovered. According to a newspaper report, the jury held that the death, while accidental, resulted from inadequate supervision and precautions against such accidents. To prevent similar accidents the jury sent recommendations to Dr. Herman N. Bundesen, president of the board of health.

Dr. Lewin Heads Department at Northwestern.—Dr. Philip Lewin, professor of bone and joint surgery at Northwestern University Medical School, has been appointed chairman of the school's department of bone and joint surgery, succeeding Dr. Paul B. Magnuson, now professor emeritus. Dr. Lewin has been a member of the Northwestern Medical School faculty since 1918. He has served as orthopedic surgeon at Michael Reese, Cook County, Municipal Contagious Disease and St. Luke's hospitals, and as orthopedic surgery professor at the Cook County Graduate School of Medicine. He was awarded the certificate of merit by the American Roentgen Ray Society in 1939. Dr. Lewin served in the army medical corps in World Wars I and II. He is author of several textbooks.

Cancer Research at University of Chicago.—More than 115 cancer research projects are under way at the University of Chicago, Dr. Leon O. Jacobson, associate professor of medicine, told the annual meeting of the trustees of the University of Chicago Cancer Research Foundation. The projects range from the basic chemistry of normal growth to the specific surgical and chemical technics for attacking various forms of cancer. The research involves work in 11 different departments of the university, including the department of botany, the Institute of Radiobiology and Biophysics and the Walter G. Zoller Memorial Dental Clinic. The trustees re-elected the present officers of the Cancer Research Foundation: Maurice Goldblatt, president; Graham Aldis, vice president; Frank McNair, treasurer, and J. Parker Hall, assistant treasurer.

KENTUCKY

Healthmobiles for Rural Areas.—The two new healthmobiles placed in service in rural Kentucky are to operate for three months in Larue and Pulaski counties. Services rendered by the traveling health centers include examination of school children, immunizations and prenatal clinics. Among the personnel will be a county health officer and a nurse.

New Mental Hospital.—Our Lady of Peace Hospital was formally opened in Louisville December 8, at which time an inspection tour was made by federal and state officials and others connected with the establishment of the $2,246,000 institution. Patients will be admitted in the early part of February. In addition to the 150 beds, the hospital has facilities for outpatients. Funds received from both the state and federal governments and contributions from Louisville citizens aided in financing the hospital.

MICHIGAN

Personal.—Dr. Warren B. Cooksey, Detroit, was elected president of the United Health and Welfare Fund of Michigan at the recent annual meeting.——Dr. Thomas H. Cooper, Port Huron, senior local district surgeon of the Grand Trunk Railroad and a member of its staff for 30 years, has been awarded the Venerable Order of the Hospital of St. John of Jerusalem. Harold E. Askew, superintendent at Port Huron, presented the award representing the Viscount Alexander of Tunis, Governor General of Canada, "Prior of the Priory" of Canada. It was the sixth time that a parchment representing the Priory "Vote of Thanks" has been given to persons outside the British Empire.

Institute of Industrial Health.—General Motors has begun a $1,500,000 research project to promote better health for its 446,000 employes and those of all American industry. It has joined with the University of Michigan in establishing the Institute of Industrial Health, whose objectives will be research, education and service in industrial medicine, health and safety. General Motors maintains 106 medical departments in as many operating units and employs 125 physicians and 675 nurses, technicians and other medical personnel, a total staff of 800 to carry out the objectives of its over-all health maintenance program. The institute will provide fellowships, scholarships and hospital residencies in industrial medicine, health and safety. Of the $1,500,000 granted the university for the institute, $500,000 will be used as needed for equipment. In addition, an annual payment of $100,000 for 10 years will be made by the corporation for research and to meet the expenses of fellowships, scholarships, added faculty and other personnel, a clinic and publications, and refresher courses for doctors, nurses and personnel in auxiliary services. The institute will begin operations within the next few weeks. It will be under the supervision and control of the board of governors to be appointed by the university's board of regents.

MINNESOTA

Plans for Care of Chronically Ill.—Taxpayers and professional groups in St. Louis County have developed a plan for better institutional medical and nursing care of long term patients. Patients will be hospitalized in three new infirmaries, which are being built adjacent to general hospitals. The county pays for construction and furnishing and then leases the buildings to nonprofit associations for operation. The welfare board pays the per diem cost for indigent patients. An infirmary of 125 beds was recently completed in Virginia, adjacent to Virginia Municipal Hospital and was leased to the Range Infirmary Corporation, organized by a taxpayers league that raised an initial fund of $50,000. The first of two planned 150 bed institutions is nearing completion in Duluth adjacent to St. Luke's Hospital. The hospital association holds a lease for the building. Admission of welfare patients is determined by the county Department of Public Assistance.

More Nitrate Deaths of Babies.—Two babies in Minnesota died recently from poisoning due to nitrates in well water used in their formulas. From July to November 14 cases of this type of poisoning were reported to the state department of health. These cases apparently constitute a new outbreak (THE JOURNAL, June 3, 1950, page 476). During 1947, 1948 and 1949 a total of 146 cases were reported, and the health department warned parents of newborn infants to be especially careful about the water used in feeding babies. They were advised to use only water from approved municipal supplies or from private sources known to be safe. For 10 months no new cases of nitrate poisoning were reported in the state; now methemoglobinemia is again occurring. As in the previous outbreak, most of the cases are reported from the southwestern corner of the state. Physicians seeing babies with methemoglobinemia are asked to notify the Minnesota Department of Health and to see that samples of the water used in the infants' feedings are sent to the health department for nitrate analysis. Copies of a reprint on methemoglobinemia, which appeared in the August 1950 issue of *Minnesota Medicine,* are available from the health department on request.

NEW JERSEY

Protein Conference.—The Seventh Annual Protein Conference sponsored by the Bureau of Biological Research, Rutgers University, New Brunswick, N. J., in cooperation with the Food and Agriculture Organization of the United Nations, will be held January 26-27. The tentative program lists the following speakers:

Ernest Geiger, Ph.D., Los Angeles, Gastrointestinal Dynamics and Utilization of Protein and Amino Acid.
Jacob A. Stekol, Sc.D., Research Institute, Lankenau Hospital, Philadelphia, Folic Acid and Vitamin B_{12} in the Synthesis and Interconversion of Certain Amino Acids and Choline.
Robert R. Scalock, Ph.D., Iowa City, Phenylalanine and Tyrosine Metabolism with Respect to Water-Soluble Vitamins.
Paul R. Cannon, Chicago, Mineral Metabolism in Relation to Tissue Protein Synthesis and the Utilization of Protein Hydrolysates.
Michel Macheboeuf, Paris, France, Newer Aspects of Protein Metabolism.
Hugh M. Sinclair, Oxford, England, Clinical Aspects of Protein Malnutrition.
Ancel B. Keys, Ph.D., Minneapolis, Human Protein Metabolism in Periods of Food Shortage.

The conference will be open to all interested persons who register.

NEW YORK

Postgraduate Lecture.—The Warren County Medical Society, meeting at the Queensbury Hotel in Glens Falls January 11 at 9 p. m., will hear Dr. Russell L. Cecil, New York, speak on "The Treatment of Arthritis." The lecture has been arranged by the Medical Society of the State of New York with the cooperation of the New York State Department of Health.

State Ties up Collections of Cancer Group.—A temporary injunction to prevent the National Cancer Hospital of America, a Detroit organization, from disposing of any funds it may have in New York State was issued by Justice Joseph A. Gavagan of the State Supreme Court November 2. According to the *Chicago Tribune,* action was sought by state Attorney General Goldstein, who said the organization began operations 11 months ago on a $2,000 loan, has grossed $600,000 in contributions from the public and has less than $100,000 on hand. Contributions were supposed to go for development and maintenance of a special cancer hospital, he said, but "there is no hospital and it is hardly likely there ever will be." Defendants in Goldstein's petition for a permanent injunction, according to the newspaper, are the cancer promotion groups; De Haan, Inc., a New York direct mail firm accused of soliciting funds for the Detroit group; Lorettamary Gibson of Detroit, founder and executive secretary of the hospital; William F. Everton of Detroit, its vice president, and Arthur H. Levien of Rockville Center, Long Island, president of De Haan. In Detroit directors of the hospital said no money has been "misapplied or misappropriated."

Isotope Distribution Center.—The University of Rochester Medical School, in cooperation with the U. S. Atomic Energy Commission and five Rochester hospitals, has established a center for distributing radioisotopes for clinical and diagnostic use in hospitals of the area. The program, which is on a nonprofit basis, was undertaken by the university as a community service. The new isotope center uses facilities of the medical school and its atomic energy project for storing, handling and processing the radioactive materials shipped from Oak Ridge, Tenn. Wide interest has been shown by the Council of Regional Hospitals, as well as hospitals in Buffalo, Syracuse, Utica, Schenectady, Albany and other areas of the country, which may lead to widening of the Rochester program. If each hospital maintained its own program the initial investment would be from $20,000 to $60,000. Under the Rochester isotope center plan, the initial cost to the individual hospital is only $1,500 to $2,000. Standard rates for physicians and hospital fees and costs per dose have been agreed on. During the development period the university and its atomic energy project have furnished a portion of the salaries of staff members plus the cost of certain equipment. It is expected that the entire isotope center activity will become self supporting in the near future.

New York City

Academy Election.—Dr. William B. Parsons was elected president of the New York Academy of Medicine for a term of two years at a meeting December 7. Dr. Henry Alsop Riley was elected vice president and Dr. Shepard Krech treasurer.

Dr. Fulton to Give Salmon Lectures.—The Thomas William Salmon Lectures of the New York Academy of Medicine will be given by Dr. John F. Fulton, Sterling professor of physiology, Yale University School of Medicine, January 9-11. They will be presented at 8:30 p. m. on successive days in Hosack Hall at the academy building. The first lecture will be on the "Functional Anatomy of the Frontotemporal Cortex," the second on "Behavioral Studies in the Higher Primates" and the third on "Frontal Lobotomy and Human Behavior."

Research on Retrolental Fibroplasia.—The National Society for the Prevention of Blindness has made a grant of $2,500 to the New York University-Bellevue Medical Center to help determine the cause of the sudden increase in the number of premature infants being blinded by retrolental fibroplasia. According to Dr. Franklin M. Foote, executive director of the society, this disease strikes most often at infants who weigh less than 3 pounds (1,361 Gm.). Before 1940, he said, retrolental fibroplasia was rare, but since then the incidence has greatly increased. One reason may be that more premature infants are being kept alive. About 650 infants are now being blinded by the disease each year.

Suburban Hospital and Medical Center Affiliate.—A fourth New Jersey hospital, Mountainside Hospital in Montclair, has affiliated with New York University-Bellevue Medical Center, under the Regional Hospital Plan, which is a part of the teaching program of the Medical Center. Under it, increased opportunities for training are also offered to all physicians practicing in the communities of affiliated hospitals. Mountainside is a voluntary general hospital having 305 beds and 61 bassinets, as well as clinics for outpatients and an accredited School of Nursing. One or more members of the hospital's intern staff will be given the opportunity to take a year's training at the center with reference to the basic sciences. These physicians are obligated to return to their hospital for at least one year following completion of the course. Mountainside has appointed Dr. Chester B. Allen, of the department of medicine, as coordinator.

Financial Report of Medical Center.—More than $7,800,000 was expended to finance teaching, research and care of patients at the New York University-Bellevue Medical Center, according to the second annual report for the year ending June 30, 1950. While an over-all operating loss of $1,332,345.41 was sustained during the year, it was possible to complete the year with no net deficit because of the generosity of individuals, foundations, business firms and organizations that supported the work. The annual report shows operating expenses for the University Hospital (formerly New York Post-Graduate Hospital), $4,635,029; New York University College of Medicine, $2,156,596 and New York University Post-Graduate Medical School, $1,061,558. The center received nearly $1,500,000 in gifts and grants for research, and it contributes at least half a million dollars to research from its own purse. Contributions amounting to $2,225,150 were received for the medical center building fund. At the end of the year the total amount contributed toward the complete goal of $32,744,000 needed for the development and construction of the medical center was $21,909,478.

PENNSYLVANIA

University Begins Psychiatric Program.—The University of Pittsburgh School of Medicine has instituted a psychiatric program. Three appointments have been made: Dr. Henry W. Brosin, professor of psychiatry and chairman of the department of psychiatry at the University of Chicago Medical School; Dr. Benjamin M. Spock, staff member and consultant in psychiatry at the Mayo Clinic, Rochester, Minn., and Dr. I. Arthur Mirsky, associate professor of experimental medicine at the University of Cincinnati College of Medicine and director of the May Institute for Medical Research. Dr. Brosin has been named medical director of the university's Western Psychiatric Institute and Clinic. He will also hold the title of professor and head of the department of psychiatry in the university's school of medicine. Dr. Spock will be professor of child development, with appointments in the department of pediatrics at Children's Hospital, the Child Guidance Center and the Graduate School of Public Health. Dr. Mirsky will head the research division of the Psychiatric Institute, which will aim at correlating biologic changes to emotion and psychiatric disorders. Dr. Brosin begins his work on January 1. Dr. Spock is scheduled to begin July 1, 1951. Dr. Mirsky will start as soon as alterations are made to the institute to provide adequate research facilities.

Philadelphia

University to Enrol Physical Therapy Students in February.—Because of the national emergency, the School of Auxiliary Medical Services of the University of Pennsylvania plans to admit students in February to a one year certificate course in physical therapy. Dean Wesley G. Hutchinson, Ph.D., said the decision was prompted by the demand for physical therapists in the U. S. military and veteran's hospitals, as well as in centers actively engaged in the treatment of infantile paralysis cases. The class will be open to college graduates having required credits in the physical and biologic sciences, psychology and social science.

First of its kind in American medical history, the new School of Auxiliary Medical Services was organized last July and officially began operations with the opening of the 1950-1951 academic year. In addition to one year courses for college graduates, the school accepts students for four year courses leading to the degree of Bachelor of Science in Physical Therapy. As presently constituted the school also trains students for careers in occupational therapy. Later it is to be expanded to include divisions for other groups of auxiliary medical workers.

Pittsburgh

Dr. Walmer Named Head of Hygiene Foundation.—Dr. C. Richard Walmer, medical director of the Industrial Hygiene Foundation, has been named managing director of that organization to succeed the late John F. McMahon. The foundation operates under the auspices of the Mellon Institute. The Industrial Hygiene Foundation is a nonprofit research organization of more than 350 companies and industrial associations for advancing industrial health, improving working conditions and bettering human relations. These members, through their affiliation with the Industrial Hygiene Foundation, are entitled to the advisory and research services of other specialists in health problems, plus the technical facilities of the Mellon Institute, where the headquarters of the foundation are located.

WASHINGTON

Public Health Statistician Needed.—The State of Washington Personnel Board is seeking a public health statistical consultant for Seattle. Applicants must have had at least three years' experience in statistical work, one year of which must have been in public health statistics. The examination will consist of a rating of education and experience. The salary range is $340 to $425. Applications should be mailed by January 22 to the State Personnel Board, 1209 Smith Tower, Seattle 4.

GENERAL

Photos of Research Animals Sought.—The National Society for Medical Research, 105 North Wabash, Chicago, will pay $5 for each photograph of animals used for research which it accepts for its new book entitled "Animals Make Medical Magic." Pictures of all types of experimental animals in laboratory surroundings are being sought.

Seminar on Psychology.—The Medical Society of Analytical Psychology will give a six session seminar in New York during January and February,, titled "Introduction to Jungian Theory and Practice." The seminars are intended for physicians and qualified psychotherapists. They will be held on six consecutive Wednesdays from January 10 to February 28 at 8:30 p. m. in the New York Academy of Medicine Building, 2 East 103 Street, New York. The following are the subjects and the speakers of the seminar:

Eleanor Bertine, New York, Jung's Concept of the Unconscious.
Werner H. Engel, New York, Basic Structural Elements of the Psyche.
Charles G. Taylor, New York, Psychological Types.
Mr. B. Minkle, Jungian Dream Interpretation.
Mr. V. de Laszlo, Goal of Jungian Analysis.
Mr. E. Harding, Principles of Jungian Psychotherapy.

The fee for the seminar is $15. Information may be obtained from Dr. Werner Engel, 123 West 74th Street, New York.

Dr. Benedict Wins Dana Medal.—Dr. William L. Benedict, Rochester, Minn., is the 1950 winner of the Leslie Dana Medal, a national award given for outstanding achievement in preventing blindness. Dr. Benedict, professor of ophthalmology at the Mayo Foundation Graduate School, was selected for recognition by the St. Louis Society for the Blind, which annually awards the medal established in 1925 by Mr. Leslie Dana of St. Louis. The medal will be presented to Dr. Benedict at a dinner in the Hotel Chase, St. Louis, January 26.

Conference on Pregnancy Wastage.—The Committee on Human Reproduction of the National Research Council will hold its annual conference January 19-20 at the Hotel Commodore, New York. The subject will be pregnancy wastage. The speakers include Drs. George W. Anderson and Robert E. Nesbitt Jr., Johns Hopkins Hospital, Baltimore; Drs. Leona Baumgartner and Ephraim Shorr, Cornell University Medical College, New York; Lester E. Casida, Ph.D., University of Wisconsin, Madison; Dr. George W. Corner and A. I. Csapo, Carnegie Institution of Washington; Drs. Stewart H. Clifford, Arthur T. Hertig and Claude A. Ville, Ph.D., Harvard Medical School, Boston; Drs. Morris E. Davis and Edith L. Potter, University of Chicago; Dr. Edward C. Hughes, State University of New York Medical Center at Syracuse; Dr. Joseph W. Jailer and Howard C. Taylor Jr., Columbia University College of Physicians and Surgeons; Dr. Philip Levine, Ortho Research Foundation, Rariton, N. J.; Dr. Christopher Tietze, National Committee on Maternal Health, Washington, D. C., and William C. Young, Ph.D., University of Kansas, Lawrence.

Section Meetings in January.—The section meetings of the American Laryngological, Rhinological and Otological Society will be held in January. The Eastern Section will meet at the Bellevue-Stratford Hotel in Philadelphia January 12 beginning at 9:30 a. m. Invited speakers include Dr. Leandro M. Tocantins, Philadelphia, who will speak on "Causes and Management of Abnormal Bleeding from the Air Passages, Associated with Disorders of the Blood," and Dr. Joseph L. Hollander, Philadelphia, "Practical Problems in Use of Cortisone and ACTH." The Middle Section meeting will be at the Hotel Cleveland in Cleveland January 15. The invited speakers and their subjects are: William D. Neff, Ph.D., Chicago, "Neural Mechanisms of Hearing," and Dr. Lee G. Eby, Rochester, Minn., "Differential Diagnostic Significance of Recruitment in Ménières Disease and Angle Tumors." The Southern section will meet at Hotel Sans Souci, Miami Beach, Fla., January 17. At the Western Section meeting January 28-29 in the San Francisco County Medical Society Building, San Francisco, the invited speakers will be:

Ottiwell W. Jones Jr., San Francisco, The Cervical Area.
John W. Cline, San Francisco, President-Elect, American Medical Association, Socialized Medicine.
John L. Wilson, San Francisco, Stenosing Esophagitis.
Seymour M. Farber, San Francisco, Medical and Cytologic Diagnosis of Bronchogenic Carcinoma.

National Multiple Sclerosis Society.—The first citation dinner for distinguished service in the fight against multiple sclerosis was held at the Waldorf-Astoria Hotel, New York, December 5. Carl M. Owen, former president and chairman of the board of the society, and Ralph I. Straus, president, were cited for their leadership in making this society a force in the field of medical research. Dr. Howard A. Rusk, chairman, department of physical medicine and rehabilitation, New York University College of Medicine, was the guest speaker. The National Multiple Sclerosis Society is financing 11 research projects, including clinics at New York University-Bellevue Medical Center and Montefiore Hospital in New York, Boston State Hospital in Boston, Detroit Memorial Hospital in Detroit, and Cedars of Lebanon Hospital, Los Angeles. It also conducts professional and public education programs and renders services to multiple sclerotics with the assistance of its chapters.

FOREIGN

Campaign Against Trachoma Among Refugees.—The World Health Organization began in December the first large scale, scientifically controlled campaign for treatment of trachoma with the new antibiotics, chloramphenicol, terramycin and aureomycin, in several Eastern Mediterranean countries caring for Arab refugees. Supplies are being donated to WHO by drug manufacturers in Italy and the United States. The United Nations International Children's Emergency Fund will furnish additional quantities. The WHO program is under the direction of Prof. Giabattista Bietti of Parma University, Italy. Up to 80 per cent of the people in some districts of the Eastern and Southern Mediterranean have this disease. It is widespread in Asia as well as in the Mediterranean area and is continuously present in most Eastern European countries and several American republics. The program will eventually reach many thousands of cases and will permit precise determination of the value of each antibiotic used, the best method of administration, the optimum dosage and the financial cost of a complete trachoma campaign.

CORRECTION

Câmara Instead of Eamara.—In the twenty-third footnote in the article by Hoffman in The Journal of Dec. 2, 1950, page 1160, the second author's name is Câmara, A. A., instead of Eamara, A. O.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. Feb. 13-15, April 16-17 (Part II only), June 18-20, Sept. 5-7. Ex. Sec., Mr. E. S. Elwood, 225 S. 15th Street, Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* July 20. Given simultaneously in several cities in the United States. Final date for filing application is Jan. 20. *Oral.* Coronado, Calif., April 4-7 and Memphis, Oct. 14-17. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15, Conn.

American Board of Dermatology and Syphilology: *Written.* Various Centers, Feb. 8. *Oral.* New York, April 6-8. Sec., Dr. George M. Lewis, 66 East 66th St., New York 21, N. Y.

American Board of Neurological Surgery: *Oral.* Chicago, May 1951. Sec., Dr. W. J. German, 789 Howard Ave., New Haven 4, Conn.

American Board of Obstetrics and Gynecology: Part I. Written Examination and Review of Case Histories. Various locations. Feb. 2, 1951. Final date for filing applications was Nov. 5. *Oral.* New York City, May 10-16. Final date for filing application is Feb. 2. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6, Pa.

American Board of Ophthalmology: *Written.* Various Centers, Jan. 5-6, 1951. *Oral.* San Francisco, March 11-15; New York, May 31-June 5; Chicago, October 8-13. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 25-26. Final date for filing applications was Aug. 15, 1950. Final date for receipt of Part I applications for 1951 was Dec. 30, 1950. Sec., Dr. Harold A. Sofield, 122 So. Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Written.* New York, Jan. 8-11, 1951. *Oral.* Richmond, Va., May 1-5. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City.

American Board of Pathology: *Written and Oral. Pathological Anatomy and Clinical Pathology.* Cleveland, April 23-24. Final date for filing application is March 15. Sec., Dr. Robert A. Moore, 1402 S. Grand Blvd., St. Louis.

American Board of Pediatrics: *Written.* Jan. 19. Under local monitors. Only written examination to be given during 1951. *Oral.* New Orleans, March 2-4. Ex. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Proctology: *Part I in Anorectal Surgery and Proctology.* Kansas City, Minneapolis, Philadelphia and San Francisco, May 12. Sec.-Gen., Dr. Louis A. Buie, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Atlantic City, June 5-9. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various centers, March 1951. Final date for filing applications was Dec. 1, 1950. *Written.* Various centers, Oct. 1951. Final date for filing applications is July 1. Sec., Dr. J. Stewart Rodman, 225 South 15th Street, Philadelphia.

Board of Thoracic Surgery: *Written.* Various Centers, Feb. 17. Final date for filing application is Feb. 1. *Oral.* New York City, April 19. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit.

American Board of Urology: Chicago, Feb. 10-14, 1951. Final date for filing applications was Sept. 1, 1950. Chicago, Feb. 9-13, 1952. Final date for filing applications is Sept. 1. Sec., Dr. Harry Culver, 314 Corn Exchange Bldg., Minneapolis 15.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Palmer House, Chicago, Feb. 12-13. Dr. Donald G. Anderson, 535 N. Dearborn St., Chicago 10, Secretary.

National Conference on Rural Health, Peabody Hotel, Memphis, Tenn., Feb. 23-24. Dr. F. S. Crockett, 535 N. Dearborn St., Chicago 10, Chairman.

* * *

American Academy of Allergy, Hotel Statler, New York, Feb. 5-7. Dr. Walter S. Burrage, 208 E. Wisconsin Ave., Milwaukee 2, Secretary.

American Academy of Orthopaedic Surgeons, Palmer House, Chicago, Jan. 27-Feb. 1. Dr. Harold B. Boyd, 122 S. Michigan Ave., Chicago 3, Secretary.

American Society for Surgery of the Hand, Palmer House, Chicago, Jan. 26. Dr. Joseph H. Boyes, 1401 S. Hope St., Los Angeles 15, Secretary.

Atlanta Graduate Medical Assembly, Municipal Auditorium, Atlanta, Ga., Feb. 5-7. Mrs. Stewart R. Roberts, 768 Juniper St. N.E., Atlanta, Executive Secretary.

Central Surgical Association, Chicago, Feb. 22-24. Dr. James T. Priestley, Mayo Clinic, Rochester, Minn., Secretary.

International Post-Graduate Medical Assembly of Southwest Texas, Municipal Auditorium, San Antonio, Jan. 23-25. Dr. John H. Hinchey, P. O. Box 2445, San Antonio 6, Secretary.

Middle Atlantic States Regional Conference, Philadelphia, Jan. 18. Dr. William Bates, 2029 Pine St., Philadelphia 3, Secretary.

National Conference on Medical Service, Palmer House, Chicago, Feb. 11. Dr. R. E. Fitzgerald, 2218 N. Third St., Milwaukee 12, Secretary.

Sectional Meeting, American College of Surgeons, Hotel Statler, St. Louis, Jan. 22-23. Dr. James Barrett Brown, 508 N. Grand Blvd., St. Louis, Chairman.

South Central Branch, American Urological Association, Hotel Adolphus, Dallas, Jan. 29-Feb. 2. Dr. Rex E. Van Duzen, 721 Medical Arts Bldg., Dallas, Chairman.

DEATHS

Hutchinson, Rollo Wilson ⊕ Medical Director, Captain, U. S. Navy, Vallejo, Calif.; born in Milford, N. H., April 27, 1891; Harvard Medical School, Boston, 1917; entered the Naval service in June 1917 as lieutenant (jg); during his 33 years of active service served at many hospitals in the United States; during World War I served at the Naval Hospital, Newport, R. I.; served on the *USS Comfort, Mercy, Concord, Detroit* and *Colorado;* prior to hospitalization was assigned to the Commander General, Department of the Pacific; specialist certified by the American Board of Radiology; member of the American College of Radiology; died in the U. S. Naval Hospital, Oakland, November 13, aged 59, of coronary thrombosis.

Jackson, John Bert ⊕ Kalamazoo, Mich.; born in Cooper, Mich., June 11, 1876; Rush Medical College, Chicago, 1903; past president of the Michigan State Medical Society; member of the American Trudeau Society, American Roentgen Ray Society, Radiological Society of North America and the American College of Radiology; fellow of the American College of Physicians; specialist certified by the American Board of Radiology; served as health officer, city physician and president of the civic league; affiliated with Bronson Methodist and Kalamazoo State hospitals and Borgess Hospital, where he died November 3, aged 74, of arteriosclerotic heart disease.

Mitchell, Lang Allen ⊕ Stillwater, Okla.; born in Haleyville, Ala., May 20, 1881; University of Nashville (Tenn.) Medical Department, 1908; president of the Oklahoma State Tuberculosis Association; past president of the Payne County Medical Society; served during World War I; for many years served in the medical reserve corps and in the Oklahoma National Guard; college physician at the Agricultural and Mechanical College from 1925 to 1928; city health officer from 1927 to 1932, formerly county health officer; affiliated with Stillwater Municipal Hospital, where he died September 14, aged 69, of a ruptured abdominal aortic aneurysm.

Hunter, Norman McLeod, Hudson, Mass.; born in Alberton, Prince Edward Island, Canada in 1872; McGill University Faculty of Medicine, Montreal, Canada, 1901; member of the American Medical Association; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; for many years president of the Hudson Community Health Association; president of the Hudson National Bank; trustee of the Hudson Savings Bank and director of the Hudson Cooperative Bank; trustee of the Marlboro (Mass.) Hospital, where he died November 5, aged 77, of coronary thrombosis.

Elkins, William Harry, Topeka, Kan.; Barnes Medical College, St. Louis, 1903; member of the American Medical Association; for many years on the staff of the Atchison, Topeka, and Santa Fe Railway Hospital, where he died September 1, aged 83, of arteriosclerotic heart disease and nephrosclerosis.

Frank, Arthur, New York; Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn, Prussia, 1919; member of the American Medical Association; on the staff of St. Elizabeth Hospital; died September 25, aged 60, of heart failure.

Hall, Myron Foster, Elmira, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1899; died recently, aged 75, of carcinoma.

Jaffe, Benjamin Meyer ⊕ Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons of Baltimore, 1916; died recently, aged 55.

King, Clayton T., Greenfield Center, N. Y.; Albany (N. Y.) Medical College, 1898; died in Porter Corners recently, aged 73, of ulcer of the cecum.

Nevins, Susan, Lawrenceburg, Ky.; Southwestern Homeopathic Medical College and Hospital, Louisville, 1901; died in the Good Samaritan Hospital, Lexington, recently, aged 74, of coronary occlusion.

Oguri, Kanzo, Brooklyn; New York Homeopathic Medical College and Flower Hospital, New York, 1920; affiliated with Brooklyn Cancer Institute and Prospect Heights Hospital; died October 24, aged 58.

Potthoff, Ernest William, Titusville, Fla.; Rush Medical College, Chicago, 1902; at one time practiced in Oak Park, Ill.; died October 12, aged 72, of coronary occlusion and cerebral thrombosis.

Robbins, Nelson John ⊕ Negaunee, Mich.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; served as mayor, city health officer and county physician; died October 25, aged 81, of heart disease.

Shaw, Robert Eugene, Whatley, Ala.; Medical College of Alabama, Mobile, 1898; member of the American Medical Association; died in Providence Hospital, Mobile, October 21, aged 79, of hypertrophy of the prostate.

Sherlock, William Paul ⊕ Hines, Ill.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1908; served during World War I; associated with the U. S. Public Health Service from 1920 to 1925, when he joined the Veterans Administration; died in the Veterans Administration Hospital October 22, aged 65, of malignancy of the gastrointestinal tract.

Sherman, Henry S., ⊕ Chicago; Rush Medical College, Chicago, 1917; an Associate Fellow of the American Medical Association; specialist certified by the American Board of Obstetrics and Gynecology; member of the Central Association of Obstetricians and Gynecologists; served during World War I; associate in clinical obstetrics at the Chicago Medical School; on the staff of the Mount Sinai Hospital, where he died October 28, aged 60, of acute myocardial infarction.

Slavich, John Francis, Oakland, Calif.; Medical Department of the University of California, San Francisco, 1904; member of the American Medical Association; served as councilman and as mayor; died in Providence Hospital October 2, aged 69, of cancer.

Smart, Elliott Plummer ⊕ Murphys, Calif.; College of Physicians and Surgeons, Los Angeles, 1912; fellow of the American College of Chest Physicians, American College of Physicians and the American Trudeau Society; served during World War I; medical director and superintendent of Bret Harte Sanatorium; formerly chief of tuberculosis service, San Joaquin General Hospital, French Camp; died October 13, aged 65, of cerebral hemorrhage.

Stowe, LeRoy, Colonial Beach, Va.; Medical Department of Tulane University of Louisiana, New Orleans, 1906; died in Washington, D. C., October 24, aged 72, of myocardial infarction.

Street, Charles Edward ⊕ Springfield, Mass.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; served during World War I; died in the Pittsfield (Mass.) General Hospital October 14, aged 77, of coronary thrombosis.

Talbot, Francis Farron ⊕ Niagara Falls, N. Y.; Georgetown University School of Medicine, Washington, D. C., 1939; on the staffs of the Memorial Hospital and Mount St. Mary's Hospital, where he died October 23, aged 36, of carcinoma of the stomach.

Thorne, Lewis ⊕ New Haven, Conn.; Yale University School of Medicine, New Haven, 1936; assistant clinical professor of psychiatry and mental hygiene at his alma mater; certified by the National Board of Medical Examiners; member of the American Psychiatric Association; served during World War II; shot and killed October 8, aged 42.

Walker, Albert Gould ⊕ San Diego, Calif.; University of Colorado School of Medicine, Denver, 1908; member of the American Trudeau Society; served during World Wars I and II; for many years affiliated with the Veterans Administration; surgeon, U. S. Public Health Service from 1920 to 1924; died October 14, aged 67, of coronary sclerosis.

Ward, Charles Douglas ⊕ Augusta, Ga.; University of Georgia Medical Department, Augusta, 1920; formerly assistant professor of clinical surgery at his alma mater; member of the American Association of Industrial Physicians and Surgeons; served on the staff of University Hospital; died October 12, aged 60, of coronary thrombosis.

Ware, Hugh Marshall, Warmsprings, Mont.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1910; member of the American Medical Association; served during World War I; affiliated with Montana State Hospital; died in St. James Hospital, Butte, October 9, aged 66, of heart disease.

Watt, Robert, Wenonah, N. J.; Jefferson Medical College of Philadelphia, 1897; member of the American Medical Association and the Medical Society of the State of Pennsylvania; served during World War I; for many years practiced in Philadelphia, where he was affiliated with the Frankford, Northeastern and Friends hospitals; died October 11, aged 80, of coronary occlusion.

⊕ *Indicates Fellow of the American Medical Association.*

FOREIGN LETTERS

LONDON

(From a Regular Correspondent)

Oct. 30, 1950.

The Food We Eat

Under this heading a correspondent, writing to the *Lancet* in a recent edition, supports previous correspondence which says that a change is taking place in our feeding habits that may be having physiological as well as social consequences. The correspondent is Dr. W. R. Thrower of London. Rationing, he says, probably expedited a social trend apparent before the war toward the popularity of snack bars. Meals obtained in these places usually consist of some form of carbohydrate with a relish of some kind. This type of meal provides a striking similarity to the meal of the Oriental, which is notoriously deficient in fat and first class protein, a circumstance believed to exert a profound effect on national vigor.

In days gone by, most artisans started the day with a breakfast which consisted largely of pork and had a midday meal usually of the packed variety, which though simple, was of a nutritional quality now difficult to achieve. In the evening a third meal was taken. Today, for breakfast, many persons get hardly anything at all or hurriedly eat a cereal; little wonder that teabreaks and other interruptions are frequent. Often these interludes are decried, but probably they reflect an unconscious desire to satisfy physiological demands. Break privileges may be abused and restrictive practices may be in operation, but he adds, he is concerned only with the medical side of the problem.

Anyone who has observed or worked with men doing continuous work of one kind or another recognizes that in recent years, despite a will to work, staying power has deteriorated. There is an insidious fatigue that creeps on in the evening and brings activities to a close, whereas in the past workers would willingly put in overtime. The extra rations, the correspondent points out, granted to certain manual workers is an official admission that something extra is needed, but somehow in practice this desired end is not achieved. When a man decided for himself the diet which best suited him in his work, he could get it. He sums up by saying that popular exhortations to increase production may prove more effective when the protein bait is more than a piece of cheese.

Vitamin A Deprivation in Man

In a recent issue of the *British Medical Journal* there is reviewed what is called one of the longest and most laborious nutritional experiments yet to be undertaken in this country. The experiment was carried out by the Medical Research Council. The investigation was stimulated by anxiety felt about the ability of the wartime diet to maintain the health of the population. The consumption of vitamin A had been increased by the Ministry of Food. Strenuous efforts in advertising campaigns to popularize carrots had been carried out. An insurance against severe deficiency was also provided by the compulsory addition to margarine of vitamin A concentrates, which were mostly obtained from whale livers. However, the article continues, doubts still remain about the exact amount of vitamin A required by human beings. In 1942 the Medical Research Council was requested to undertake experiments to obtain definite information on this point. The report of the investigation, which was organized by the Vitamin A Subcommittee of the Accessory Food Factors Committee, was given the title "Vitamin A Requirements of Human Adults: A Study of Vitamin A Deprivation in Man."

Twenty young male conscientious objectors and three women acted as volunteers. They were housed at the Sorby Research Institute, Sheffield, in a large villa with some rooms converted for use as laboratories. Organization of the investigation was in the hands of Dr. Kenneth Mellanby and subsequently of Prof. H. A. Krebs. Most of the volunteers had already proved their reliability in experiments on the transmission of scabies, and they tolerated without protest a monotonous diet made deficient in vitamin A and carotene by exclusion of foods such as butter, whole milk and its products, liver and other animal organs, fat, fish and all green and yellow vegetables and fruits. Laboratories at Cambridge, Liverpool, Oxford and Reading cooperated, and numerous routine tests for vitamin A and carotene were carried out, both on the blood and feces of the volunteers and on the foodstuffs they were allowed to consume. Apparatus was designed by Mr. W. Bartley, one of the volunteers, for measurement of the capacity for dark adaptation. The scope of the investigation can be judged by the size of the research team, which consisted of about 25 doctors, scientists and senior technicians, with the aid of many commercial firms, which provided specially prepared foodstuffs and also helped in other ways. The heavy task of coordinating the efforts of the various workers was done by Miss E. M. Hume.

Sixteen of the volunteers subsisted on the diet without any supplements, and two were given preformed vitamin A. Carotenoid pigments disappeared from the blood of these subjects almost completely during the first few weeks of the experiment. The decline in plasma vitamin A, which had in the first instance ranged from 65 to 120 international units per 100 ml., was much less rapid, and in one subject the original vitamin A blood level was maintained for no less than 22 months. The mean figure of 88 international units was obtained from tests made shortly after the experiment had started.

This fell to 74 international units in nine months. In seven subjects remaining under experimental conditions for 14 months the mean was still as high as 61 international units. The decline in both plasma carotenoids and vitamin A was prevented or reduced in control subjects by daily doses of 2,500 to 6,700 international units of carotene in various forms, while the fall in plasma vitamin A, but not the carotenoids, was prevented by doses of 2,500 international units of a distilled concentrate of vitamin A esters. In the parallel tests performed on these control subjects, some evidence was obtained of a seasonal variation in dark adaptation. Only three of the volunteers showed a deterioration in dark adaptation that was unrelated to the season of the year; all these three had plasma vitamin A values of 40 international units or less. Only in these cases was it possible to carry out satisfactory therapeutic tests. Preformed vitamin A, in a daily dose of 1,300 international units, was given over a prolonged period and was found to improve dark adaptation and to restore the plasma vitamin A to about its original level. With a daily dose of 1,250 international units of carotene in oily solution the amounts of vitamin A and carotenoids in the plasma were slightly increased, but dark adaptation was improved only when the dose was raised to 2,500 international units. The efficiency of absorption of carotene from carrots and green vegetables was determined by comparison of the amounts eaten and those excreted in the feces. With allowance for a safety margin and for wastage during absorption the daily requirement of an adult male may be assessed as 2,500 international units of preformed vitamin A, 4,000 international units of carotene in oil, 7,500 international units of carotene in green vegetables, or 12,000 international units in boiled sliced carrots. With ordinary diets, of course, the daily requirement will not be derived from a single item but will be contributed by foods containing both preformed vitamin A and carotene. Larger amounts of the vitamin may be needed by pregnant or lactating women and by children.

Apart from the changes mentioned the volunteers had no symptoms which could be ascribed to deficiency of vitamin A, though during the experiment two of them were found to be suffering from tuberculosis. While it may seem surprising that a diet containing only traces of the vitamin should have caused no symptoms of deficiency in most of the subjects, it has long been known that the human liver normally contains large amounts of vitamin A. In England before the war, Moore found that the reserves present in the liver of persons who died as a result of accidents usually appeared to be sufficient to meet body requirements for several months, and there is nothing in the Medical Research Council's report to indicate that wartime dietary changes have had the effect of decreasing reserves. It is, however, surprising that some of the volunteers were able to subsist on this restricted diet for one and a half to two years.

From this one must conclude, the article continues, that the reserves of the liver are mobilized and expended with great economy by the body. The clear evidence of incipient vitamin A deficiency found in three out of 16 subjects was perhaps as much as could be expected from an experiment which could not be prolonged indefinitely.

FLORENCE, Oct. 20, 1950.

Present Development of Tomography

One of the most interesting scientific reports at the International Medical Meetings of Verona was a discussion by Professor Vallebona, director of the Institute of Radiology of the University of Genoa, of the origin and development of tomography. He pointed out that the common roentgen examination deals with the superimposed shadows of various parts of the body and, although the outlines of the more opaque organs and structures predominate, other outlines of more transparent parts overlap into their shadow. A complex picture results, in which it is not always possible to differentiate the radiographic contour of a certain organ or layer. Tomography, on the other hand, permits observation of a selected plane of an organ, eliminating shadows of structures situated in other areas.

The first patents for this new system of investigation were issued during the years 1921 to 1927 in France and in Germany. The first publication on the subject was that of Professor Vallebona, in February 1930, which included reproductions of the first tomograms made. At the Ninth Italian Congress of Radiology held in Turin in May 1930, the speaker discussed his preliminary results and stressed that with this new technic it was possible to examine almost separately the various regions of the base of the skull, largely avoiding superimposition of shadows.

Vallebona claimed priority in 1932 and was later given general recognition. In 1934, Grossmann and Chaoul designed an apparatus that was widely adopted in various countries. On the occasion of Vallebona's report to the Congress of Radiology of Turin (1930), Professor Busi proposed the name "stratigraphy" for this method, a term since adopted in Italy. Various terms have been used in foreign countries, such as planigraphy, tomography and laminography, as the American authors prefer. The methods are fundamentally the same, being based on a single principle, which consists in moving the patient or the patient and the plateholder or the complex x-ray tube to eliminate the shadows of layers that are of no interest. The movements may be more or less complicated, according to the variations of the method, but the types of movements may be reduced to two categories according to whether the elimination of the shadows is obtained with unidirectional or multidirectional movement. Theoretically, preference should be given to multidirectional movement, since it best eliminates the disturbing shadows. However, the unidirectional movement permits a shorter exposure time and is easier in practice. The direction of the movement should be selected according to the region of the body that is being studied. In principle, it is preferable to keep the patient quiet, moving the x-ray tube and the film.

Tomography has its greatest practical application in the study of the chest, especially in pulmonary tuberculosis. In this it offers the following main advantages over normal roentgenograms: (1) demonstration of lesions in cases unrevealed by the customary examination, (2) study of the finer details of lesions already demonstrated by customary examination and (3) elimination of erroneous results caused by superimposition of shadows.

The method has been considerably improved, making it possible to obtain tomograms in a plane perpendicular to the axis of the body. This method of examination, "transverse axial stratigraphy," was achieved by Vallebona in 1947. It is part of the regular studies at the Institute of Radiology of the University of Genoa, a special instrument built by Zuder, the "pantix-strator," being used.

Clinical Polymorphism in Salmonellosis Epidemics

Drs. Scotti and Sicca reported to the Medico-Surgical Society of Pisa on the appearance of various syndromes in the course of salmonellosis epidemics. The speakers studied eight minor epidemics. Bacteriologically, Salmonella typhimurium, S. enteritidis, S. derby and S. paratyphi have been isolated. Clinically, septic (many fatal), typhoid and acute gastroenteric forms were observed. Among the latter, five cases were of a choleriform type (one fatal), two were complicated by hepatorenal syndromes, two by glomerulonephritic syndromes and two were of a mild enterocolitic type. The speakers showed that this variety of clinical forms has been observed in the course of every epidemic outbreak. Variations should not therefore be attributed to the type of the infectious species or to different strains of the same species. They did not find any substantial evidence that the diversity of clinical forms observed may be related directly to the bacterial attack or to toxins that might have been involved.

Professor Pavlov's Centenary

The University of Rome commemorated the centenary of the birth of the physiologist Pavlov. At the Institute of Psychology of the Faculty of Medicine, a display on the scientific work of the great physiologist was prepared, showing through photographs, graphic illustrations and drawings the fundamental contributions made by Pavlov during his long period of activity as investigator in the various fields of physiology and of psychology. Martino, professor of physiology and rector of the Universiy of Messina, gave the commemorative speech, discussing Pavlov and the importance of his work as a physiologist and stressing its original creative quality.

Professor Ponzo, director of the Institute of Psychology of the University of Rome, discussed the ingenious discoveries of Pavlov in the field of psychology. The direction given by Pavlov to psychological thinking constitutes one of the fundamental bases of contemporary psychology, having given rise to behaviorism.

DENMARK

(From a Regular Correspondent)

COPENHAGEN, Oct. 23, 1950.

Hospital Ship for Korea

Shortly after the outbreak of war in Korea, Denmark expressed a desire to participate on the side of the United Nations. To the suggestion that Denmark should provide a field hospital, it was pointed out that the country could not dispense with such a fully trained unit at the time. So a compromise was reached according to which Denmark should send a fully equipped hospital ship. The president of the Danish Red Cross, Commander Hammerich, an ex-naval officer, undertook command of this unit and *Jutlandia*, a motor boat of about 8,500 tons, was chartered by the Danish government with the understanding that the Danish Red Cross should be responsible for the organization and management of this unit. Dr. Karl Lehmann took an active part in the negotiations leading up to this arrangement.

Jutlandia is a combined passenger and cargo ship with a crew of about 100. Its passenger cabins, being too small to serve as hospital wards, are to be reserved for the members (about 100) of the Red Cross staff. Six comparatively large wards provide space for 200 hospital beds, and there is to be a reserve of some 50 other hospital beds. Two elevators, each accommodating six stretchers, are being built into the ship, and the middecks are being altered to provide operation theaters and various other rooms needed for anesthesia, radiologic examinations and the like. The hospital staff will include about 15 doctors, divided between a large surgical department and a smaller medicoepidemiological department. On the surgical side there will be three operation teams, with three surgeons on each. They will include general surgeons and specialists in surgery of the brain and lungs. There will be altogether 40 nurses as well as about 30 male and female orderlies. With a ship's chaplain and many other persons specializing in the material and spiritual needs of a modern community, *Jutlandia* will be a self-sufficient unit. It is estimated that the ship will not be in readiness to sail for Korea before the end of November.

Aureomycin

Reports from several hospitals published in a recent issue of *Ugeskrift Laeger* are remarkably unanimous in praise of aureomycin. At the Blegdam Fever Hospital (chief: Prof. H. C. A. Lassen) treatment of virus pneumonias with aureomycin was started in December 1949. Dr. T. Hildan and Dr. S. Nörregaard have reported on 13 adults with primary atypical pneumonia diagnosed as such on the basis of the clinical picture and the refractoriness of the disease to penicillin and sulfonamides. Serving as controls were 18 adults who, according to the above criteria, had the same disease and were treated in the same hospital in 1949. While the temperature fell by crisis in the aureomycin group (in 10 cases within 12 hours), it nearly always fell by lysis in the control group. The duration of fever was also on the average shorter in the first than in the second group. The dyspepsia liable to follow large doses of aureomycin given by mouth was not observed when each dose did not exceed 0.5 Gm. A dosage of 0.5 Gm. five times a day may, it is suggested, in the future be reduced to 0.25 Gm. four times a day, and in most cases the drug may be discontinued after three or four days.

At the neurological department of St. Joseph's Hospital in Aarhus Dr. Jessen (chief) and Dr. Mosegaard have found aureomycin successful in two cases of herpes zoster of the eye. From Frederiksborg Central Hospital in Hilleröd (chief: Dr. Torben Andersen) comes a report from Dr. Ebbe Thomsen of the successful treatment with aureomycin of a 2 year old child with meningitis (caused by Pfeifferella mallei).

Treatment of Acute Tonsillitis with Penicillin

Between October 4, 1948 and June 11, 1949, a carefully controlled investigation of the effects of penicillin on acute tonsillitis was carried out at the Blegdam Fever Hospital by a team of doctors whose findings are published in a recent number of *Ugeskrift for Laeger*, the organ of the Danish Medical Association. All the patients admitted to hospital for acute tonsillitis in the period under review were sent to one or the other of two departments—a penicillin department and a control department admitting patients on alternate days. Several of the 835 patients were disqualified for this comparative study for various reasons, and there remained 507 patients, 349 of whom suffered from ordinary acute tonsillitis (group I), 132 from phlegmonous tonsillitis (group II) and 26 from tonsillitis ulcerosa (group III). The adult patients treated with penicillin were given 150,000 units twice daily for six days, the dosage for children being smaller and varying with their age. The controls were given only symptomatic treatment with confinement to bed.

The authors of this study, T. Bennike, K. Brøchner-Mortensen, E. Kjär, K. Skadhauge and E. Trolle, conclude that penicillin has a definitely beneficial effect on streptococcic tonsillitis and phlegmonous tonsillitis since fever and throat pain disappeared earlier in the penicillin-treated cases than in the controls. There was also a reduction in the penicillin-treated group in the number of pyogenic complications during the acute phase of the disease. But the penicillin-treated group did not fare better than the controls in the matter of relapses and morbid sequelae, and it would seem that penicillin had no appreciable effect in cases of tonsillitis in which streptococci were not found. This conclusion applies also to the many children thus treated. It is evident that the bacteriologic flora of the tonsils is an important factor determining success or failure with penicillin treatment.

Care of the Mentally Defective Child

In Norway, with a population of about 3,000,000, systematic efforts have been made to improve the lot of the mentally backward child for more than half a century. As Dr. Baard Brekke, secretary of the Norwegian National Association for Mental Health, has lately pointed out in a comprehensive review of the subject, there is much still to be done. Since World War II the government has encouraged the opening and successful management of small private nursing homes and "working homes" for low grade oligophrenics. In 1949 the government undertook to support such homes by a certain economic guarantee with a view to stimulating their development.

The number of oligophrenics in need of institutional care has been estimated at about 6,000. The mental equipment of some 1,200 children is regarded as inadequate for any school attendance whatever. There are also some 1,700 children of school age in need of special education (intelligence quotient approximately 50-75). About 1,600 children attend special schools, of which there are two in Oslo. These schools are not supposed to accept children with an intelligence quotient below 70. Unfortunately, many children in need of special classes do not attend them but remain at home or are a nuisance in the ordinary elementary schools.

There are 12 reformatory schools for children and adolescents aged 9 to 18. An investigation of these schools by Dr. E. Haugen in 1937 led to some disquieting disclosures. He found normal intelligence in only 15 per cent, and in 62 per cent he found an intelligence quotient below 75. It was below 50 in 7 per cent. His investigations led to the appointment of a state commission, which in 1939 proposed a whole series of reforms, with greater discrimination in the selection of candidates for these schools. These are just a few of the items of information entering into the machinery of a widespread scheme for dealing systematically with every aspect of the problem of the mentally defective child. Other aspects of this problem will be discussed later.

Death of Dr. Jersild

An obituary notice of Dr. Olaf Jersild (born July 6, 1867; died May 27, 1950), who was head of the Rudolph Bergh Hospital in Copenhagen in the period of 1916-1937, brings out the interesting fact, unfamiliar to many of his junior colleagues, that it was on his initiative that the system of centralizing all the notifications of syphilis in the serologic department of the State Serum Institute was adopted throughout Denmark. When this system was first proposed during World War I, considerable opposition arose for fear that the anonymity of the patient would not be preserved. In February 1919, at a meeting of the Danish Dermatological Society, Jersild presented a scheme that, by its provision for strict anonymity, was acceptable by all. The system also satisfied the requirements of even purist statisticians. It was in operation as early as 1920 and has since then provided information of both national and international value, which has formed the basis of numerous scientific studies of syphilis.

BRAZIL

Oct. 30, 1950.

Treatment of Blastomycosis

In the Faculty of Medicine of São Paulo Dr. Carlos da Silva Lacaz performed some clinical experiments with sulfonamide drugs in the treatment of blastomycosis. He drew the following conclusions:

1. Sulfonamide therapy of blastomycosis leads to good clinical results in most cases.
2. Relatively low blood concentration in vivo of different sulfonamide compounds causes a good therapeutic effect. This fact has already been observed by Padilha Gonçalves (1946), who demonstrated the sensitiveness of Paracoccidioides brasiliensis to the fungistatic action of those substances.
3. Among the sulfonamide compounds examined in the treatment of South American blastomycosis, sulfadiazine and sulfamerazine are the best therapeutic agents.
4. It is always advisable to determine the concentration of the sulfonamide drugs in the blood to verify how much of the compound is absorbed and utilized and how many patients acquire a resistance to the product.
5. Great variations in the results were obtained with different dosages and the average daily dose and the total dose cannot be fixed inflexibly.
6. Triturated sulfadiazine gives lower blood concentrations than nontriturated sulfadiazine.
7. The combination of sulfadiazine and sulfamerazine offers great value in the treatment of blastomycosis.
8. Besides preventing the appearance of crystals in the urine, this mixture allows the use of two sulfonamides with good individual tolerance and with a high and constant blood concentration.
9. Even with high blood concentrations, sulfadiazine and sulfamerazine in vivo have not a fungicidal activity but a fungistatic one on Paracoccidioides brasiliensis.
10. It is not sufficient to give the patient with blastomycosis the sulfonamide preparations even in high blood concentration if his general conditions are not ameliorated and if his immunity against the infection is not aided.
11. The cure of blastomycosis depends principally on three factors: sufficient blood concentration of the medicament, susceptibility of the causative microbe to the sulfonamide drug used, and a sufficient number of phagocytes to engulf and destroy the parasites.
12. The immune-allergic factor in blastomycosis deserves more attention from investigators.
13. The combination of sulfadiazine and sulfamerazine is well tolerated by patients with blastomycosis; it reaches a high concentration in the blood and the healing process is completed after a relatively short time; however, relapses can occur. For that reason strict observation of the patients is necessary.

Two New Vectors of Schistosoma Mansoni

Dr. Durval T. Lucena, of the Laboratory of the Malaria Division, National Department of Health, informed the Brazilian Society of Hygiene that two snails which are common vectors of Schistosoma mansoni in South Africa, and had never before been observed in Brazil, had been recently found near Santos, state of São Paulo. In a batch of snails captured at Saboó, near Santos, by Dr. Carlos V. Dutra, at the request of Dr. Lucena, the authors discovered two species entirely different from all other snails of Brazil. The samples were sent to Prof. J. Boquaert, of the Museum of Comparative Zoology of Harvard College, with whom Dr. Lucena has been collaborating in the study of Brazilian snails. The two snails are Biomphalaria alexandrina pfeifferi Krauss and Bulinus tropicus Krauss, both vectors of S. mansoni, and the latter also of Schistosoma hematobia. The fact represents the probability of aggravation of the problem of intestinal schistosomiasis in Brazil, which our health authorities are already combating in the northeastern section of the country, and the possibility of creation of a new focus of the disease near Santos, where schistosomiasis has never occurred before.

A Laboratory of Embryology

Dr. Knud H. Krabbe, head of the department of neurology of the Kommunehospitalet of Kopenhagen, Denmark, is a guest of the Oswaldo Cruz Institute in Rio de Janeiro, to cooperate in the organization of a laboratory of compared embryology. During his stay Dr. Krabbe will lecture at this institute, at the National Academy of Medicine and at the Neurological Institute of Rio de Janeiro University on (1) organization of embryologic researches; (2) importance of embryology in clinical medicine; (3) morphogenesis of the cerebrum in mammals, reptiles and birds; (4) cerebrum epiphysis and the parietal organs; cerebrum paraphysis; (5) generalized diseases, congenital and hereditary; (6) inflammatory and demyelinizing diseases of the nervous system; (7) subcommissural and subfornical organs of the cerebrum, and (8) future research on the pathology of the nervous system.

Keloidian Blastomycosis

A study of a dermatosis, called keloidian blastomycosis, or Jorge Lobo's disease, was reported by Drs. Nery Guimarães and D. G. Macedo, of Instituto Osvaldo Cruz. Keloidian blastomycosis is a benign dermatosis, occurring on the American Continent and predominating in the Amazon Basin. It is a chronic disease and resistant to known therapeutic agents. It is produced by a fungus (Glenosporella loboi fonseca and leão, 1940) that is difficult to cultivate in the usual artificial mediums and is of low pathogenicity in laboratory animals. Keloidian blastomycosis occurs on the American continent between the Tropics of Cancer and Capricorn, with a large incidence of cases near the Equator. Only nine cases have been reported in 20 years. However, if the methods of diagnosis were known, principally in the Amazon region, many more cases would undoubtedly be discovered.

Spondylolisthesis

Spondylolisthesis is not as infrequent as many physicians formerly believed, according to Dr. Manoel Campanario, radiologist of Estrada de Ferro Sorocabana, São Paulo. Diagnosis is easy in the advanced cases but is difficult in the early ones. Slipping of the vertebral body can be measured by three technical methods, which he has described. The roentgenologic technic requires many views with the patient in the anteroposterior, oblique and lateral, recumbent and standing positions.

Spondylolisthesis may at times be confused with vertebral anomalies which have no pathologic significance. The clinical significance of the spondylolisthesis is varied. It can be absent, although sometimes it is remarkably apparent. In the latter cases surgical procedures are indicated.

CORRESPONDENCE

BACTERIOLOGIC ENVIRONMENT IN CHRONIC OR REPEATED INFECTIONS

To the Editor:—The recent publication of my bacteriologic studies on patients suffering from respiratory infections (Prigal, S. J., and Molomut, N.: Bacteriologic and Epidemiologic Approach to the Treatment of Respiratory Infections with Antibiotic Aerosols, J. A. M. A. 144:897 [Nov. 11] 1950) prompts this communication, since some time will elapse before the detailed clinical studies will be reported.

The role of the environment in the production of disease has many facets, including socioeconomic and bacteriologic. It is with the latter that this communication is concerned, since it is my opinion that chronic or repeated respiratory infections are improperly diagnosed and treated in many cases. It is insufficient to diagnose chronic bronchitis, chronic infective asthma or chronic sinusitis. What organism or organisms are involved? What antibiotics can be employed? Does the patient reinfect himself from a focus such as a chronic blepharitis or conjunctivitis? Is there a carrier nearby that reinfects the patient? One must utilize for these chronic cases accepted principles of public health employed in combating contagious diseases of serious import. Ordinarily these illnesses do not threaten life directly, but they do take a terrific toll in the number of persons involved and the debility produced.

In the case of an infant of 12 months who has had repeated attacks of tonsillitis since the age of 1 month and for the past six months has had asthmatic bronchitis, bacteriologic investigations strongly implicated the mother as the source of the child's illness, since she has had no less than six acute attacks of purulent conjunctivitis in the past year. Although apparently "cured," the eye still yields a hemolytic Staphylococcus as does her pharynx. Is it mere coincidence that repeatedly one can culture a pathological Staphylococcus from the infant's pharynx?

A girl of 5 has had repeated colds since the earliest days of her life, with two episodes of bronchopneumonia and, more recently, asthma following each rather frequent "cold." She will probably continue to have these episodes in spite of allergic investigations and proper antibiotic therapy, because she has a loving mother who also has been subject to "colds" since childhood—very mild, to be sure—and who always sniffles and hawks. The patient will be lucky if in her later years she avoids bronchiectasis and does not become chronically ill. Is it coincidence that both mother and child yield on culture beta hemolytic streptococci and beta hemolytic Proteus vulgaris? Cultures taken from the father reveal beta hemolytic streptococci and hemolytic staphylococci, although he is asymptomatic. Is the child being exposed to a double hazard? Quite possible.

These observations need not be limited to children; I have observed a wife who has had severe asthma and probably some bronchiectasis for three years. Repeatedly a hemolytic Staphylococcus has been cultured from the pharynx and from an eye which is subject to repeated conjunctivitis and blepharitis. One might consider it coincidental that the same organism is obtained on culture from the pharynx of the husband, who has no real complaint other than nasal stuffiness and postnasal drip. The history reveals, however, that after each hospitalization there is remarkable abatement of symptoms. Is this due to the separation from the husband, a possible carrier, or has there been avoidance of some allergenic contact at home? The solution suggests itself readily by this episode. In view of the severity of the asthma following each cold, the patient was sent to Florida for the winter, where she did remarkably well until the husband came for a brief visit. She caught cold again and was in misery for the rest of the winter. The patient is getting along well at home now while the husband is subjected to antibiotic therapy.

More pertinent is the family of five now under consideration, in which two of the children, boys aged 12 and 10, have asthma of the mixed type due to pollen and other specific sensitivities as well as to secondary infection. The older one has sinusitis, the younger has periodic bouts of fever without any apparent cause other than a red pharynx. The youngest child, aged 5, has frequent attacks of tonsillitis; she never quite loses her "cold" during the winter. The mother had a "cold" recently of long duration but not disabling and has been left with a mild cough. The father, a hay fever victim, has become accustomed to nasal symptoms even though they continue beyond the ragweed season. All five members of the family have yielded by pharyngeal culture a hemolytic Streptococcus. The father and sons have a hemolytic Staphylococcus. The clinical story is suggestive of contagion. The mother became ill, then each of the children in turn had a respiratory illness. The father was the only one not disabled. Is he the carrier?

Although I have emphasized infective asthma in the aforementioned cases, the same factors undoubtedly prevail in chronic bronchitis, bronchiectasis and sinusitis. And one can go further than respiratory diseases and investigate the bacteriologic environment in rheumatic fever, nephritis and other diseases produced or aggravated by infection. This bacteriologic approach raises the question about the true evaluation of the role of heredity in such diseases as asthma and rheumatic fever. Suspecting heredity simply on the frequency of occurrence of a specific disease within the family unit is not entirely valid in the case of diseases due to infection. One must consider the bacteriologic environment; otherwise, one must perforce postulate a hereditary susceptibility to illness, always difficult to prove.

Two factors stand out in observations on the carrier state made by Molomut and me. The first is that the dominant but not exclusive organism is the hemolytic Staphylococcus, as noted in many of my cases. This organism is hardy, frequently resistant to penicillin and some of the other antibiotics, and, because it ordinarily does not threaten the life of the host, it does not produce sufficient immunity to destroy the organism. Thus, there is established a continuing parasite-host relation—the host is now a carrier. Second, the carrier or carriers should be treated simultaneously with the patient. Although the organisms may be morphologically identical, the reaction to antibiotics may differ. One observes frequently hemolytic staphylococci, in children, resistant to penicillin (owing to its frequent and inadequate use), whereas the same organisms, in the untreated parent (carrier), are still sensitive to that antibiotic. Our investigations continue and will be reported in detail at a later date.

Samuel J. Prigal, M.D.,
55 Park Avenue, New York 16.

SALT-FREE DIET

To the Editor:—In recent numbers of THE JOURNAL there have appeared many controversial papers and letters about the role and value of the salt intake and restriction of hypertensive patients. For Frederick M. Allen the etiological role of salt excess seems to be established, while Paul D. White and his associates and Arthur M. Master and co-workers hold that efforts to lower the blood pressure by means of drugs or strict low sodium or rice diets may be unnecessary for most hypertensive persons.

One is astonished that in all the numerous papers about this subject no reference is made to the methods of the French school. Pasteur Vallery-Radot writes in his booklet "Premières vérités (ou soidisant telles) des maladies de renies" (1937) that the French determine whether the patient has a dry or humid retention of sodium or chloride and prescribe a rigorous salt-free diet only if the patient has proved retention. They have two methods of determining whether there is retention. In the light of these concepts the problem is simple enough: it is advisable to restrict the intake of salt by hypertensive persons to prevent retention, but a salt-free diet is necessary only in cases of proved retention. It is clear that the salt-free diet can alleviate only the symptoms due to retention of salt and cannot have any influence on troubles caused by the hypertension itself or the concomitant arteriosclerosis.

SAMUEL KRAUS, M.D., Kfar Neter, Israel.

BOOK ON THE SEXUAL CRIMINAL

To the Editor:—The review of the Sexual Criminal in THE JOURNAL of October 28 has been brought to my attention. This book should have been reviewed with a strong condemnatory note. It is complete nonsense from a medical point of view and is obviously designed to appeal primarily to sadomasochists. How the lurid picture of a dismembered arm or leg would help explain sexual crime is difficult to understand. Under rogues gallery pictures there are such ridiculous statements as "note the curled lip and dreamy eyes typical of the sexual offender."

MANFRED S. GUTTMACHER, M.D.,
Chief Medical Officer, Medical Service of the
Supreme Bench of Baltimore,
Court House, Baltimore.

FREE MEDICINE

To the Editor:—I am sending you a direct quotation from a letter I received from a patient who recently went to England to visit her son, who is stationed there.

"The reason I'm writing you is that I have finished the pills that you gave me to bring along to England, and now I've taken the prescription to the druggist here and they say I would have to go to a Dr. first and then bring it back to them on account of the national health clinics here, so I went three times and could not get attended to on account of the waiting list. Would you kindly send me some by air mail enough to last me the remainder of my stay here."

G. VERNON JUDSON JR., M.D.,
213 Clements Bridge Road, Barrington, N. J.

PERIPHERAL FACIAL PALSY

To the Editor:—I read with interest the article of Dr. Theodore T. Stone on peripheral facial palsy (multiple attacks in three brothers) in THE JOURNAL (**143**:1154 [July 29] 1950). His statement that familial and hereditary factors are not mentioned in the literature is, however, not true. In 1947 I reviewed the literature on the hereditary disposition for neuritis and I mentioned a family that I had observed, in which a brother, a sister and a son of the brother had facial palsy (Over families met hereditaire dispositie tot het optreden van neuritiden gecorreleerd met migraine, *Psychiat. en Neurol. bl.* No. 1/2). I was the first to describe on this occasion a syndrome seen by me in two families with hereditary disposition for neuritis associated with migraine. Dr. Stone writes: "In 1 patient (case 2) in addition to two attacks of Bell's palsy (neuropathy of facial nerve) there occurred two episodes of ophthalmic migraine with external ophthalmoplegia." It might be that Dr. Stone would find the same syndrome if he examined the entire family.

J. G. Y. DE JONG, M.D.
St. Jozefziekenhuis, Heerlen-Holland.

REACTIONS TO VITAMIN B_{12}

To the Editor:—No reports of local reactions to parenteral administration of vitamin B_{12} have come to my attention to date, although I have observed such an incident. The patient is a 47 year old, lean, white, ambulant woman who has had multiple radicular neuralgias for many years. Evidence of hypovitaminosis had been present even prior to cholecystectomy and posterior gastroenterostomy for chronic cholecystitis and duodenal ulcer in 1937. Doses of 7.5 micrograms of vitamin B_{12} (concentrate) were given subcutaneously in the right or left deltoid regions on March 17, March 24, April 18 and April 28, 1950, without undue effect. On May 17, she received 10 micrograms in the left arm, which was followed by pronounced swelling and pain in the arm lasting several days. On May 22 the same dose in the right arm produced a similar effect. No general effects were noted by the patient. Nodules were still present at administration sites on August 7. They were not present when I examined her on October 10.

HENRY A. ARKLESS, M.D.,

Miscellany

THE ATOM

An atom is so small that about a hundred billion billion of them are contained in the head of a pin. The nucleus—the object of study in nuclear science—is some 10 thousand times smaller than the atom. If an atom were expanded to the size of a concert hall, its central nucleus would be smaller than a housefly. The nucleus constitutes nearly all of the mass of the atom and, consequently, the mass of all things. A piece of solid nuclear material the size of a child's marble would weigh more than 200 million tons. . . .

Scientists who study the nuclei of atoms speak in terms of the following entities they are able to detect and measure:

PROTON

The nucleus of a hydrogen atom is called a proton. This particle has a positive electric charge equal numerically to the negative electric charge of the electron and is so small that it takes 2.72×10^{26} to make a pound. The nuclei of atoms of other substances contain a number of protons equal to the atomic number of the element.

NEUTRON

The nuclear particles which have no electrical charge are called neutrons. They weigh approximately the same as protons.

NUCLEON

The word nucleon means either a proton or a neutron.

BETA PARTICLE

One of the radiations found shooting out of certain radioactive materials, named the beta particle, appears to be the same kind of electron that is found in the outer structure of all atoms. It has a unit negative charge equal and opposite to the positive charge of the proton and is nearly weightless, having less than 1/1800 the mass of a proton.

POSITRON

Like the electron, the positron has a unit charge of electricity but is positive instead of negative, i. e., it has the same charge as the proton. It is evanescent, dissipating itself in a flash of radiation as soon as it encounters an electron, which disappears with it.

MESON

Predicted from theory as a particle necessary to explain the forces of nuclear structure, the meson was observed for the first time in 1936 in the violent nuclear shattering caused by high energy cosmic rays in the upper atmosphere. Several varieties exist, both positive and negative, their mass averaging about one-sixth that of the proton.

NEUTRINO

A nearly weightless particle, without charge. Like the neutron, the neutrino was predicted on theoretical grounds, but it has not yet been observed, as the neutron had not been observed before 1932 and the meson before 1936.

GAMMA RAYS

These are not particles in the same sense as those above, but flashes of electromagnetic radiation emitted by the nucleus when it has excess energy. These flashes are often called photons.

Seventh Semiannual Report of the United States Atomic Energy Commission, January 1950

Council on Medical Education and Hospitals

NEW HOSPITALS REGISTERED

The following hospitals were registered by the Council on Medical Education and Hospitals of the American Medical Association at its meeting in Cleveland, Dec. 4, 1950.

Alabama

George H. Lanier Memorial Hospital, Langdale
Davis Clinic-Hospital, Leeds
Leeds Hospital, Leeds
Oak Street General Hospital, Montgomery
Mizell Memorial Hospital, Opp

Arizona

Casa Grande Hospital, Casa Grande
Douglas Hospital, Douglas
Safford Inn Hospital, Safford

Arkansas

Veterans Administration Hospital, Little Rock
Howard County Memorial Hospital, Nashville

California

Pioneers Memorial Hospital, Brawley
Mount Sinai Hospital and Clinic, Los Angeles
Temple Hospital, Los Angeles
Butte County Hospital, Oroville
Sierra Madre Lodge, Pasadena
Maimonides Health Center for Chronic Sick, San Francisco
Santa Rosa Memorial Hospital, Santa Rosa

Colorado

Montrose Memorial Hospital, Montrose
Rangely Community Hospital, Rangely
Routt County Memorial Hospital, Steamboat Springs
Yuma Community Hospital, Yuma

Florida

Miami Hospital, Miami

Georgia

Memorial Hospital, Adel
Huey Hospital, Homerville
Dr Kitchens Clinic Hospital, LaFayette
Kennestone Hospital, Marietta
Stewart Webster Hospital, Richland
Cobb Memorial Hospital, Royston
Conner Bedingfield Hospital, Vidalia

Idaho

Bingham Memorial Hospital, Blackfoot
Caldwell Memorial Hospital, Caldwell
Valley County Hospital, Cascade
Memorial Hospital, Weiser

Illinois

Ida Mae Scott Hospital, Chicago
Longwood Convalescent Home, Chicago
Orthodox Jewish Home for the Aged, Chicago
Rest Haven Convalescent Home, Chicago
Fairfield Memorial Hospital, Fairfield
Abbott House, Highland Park
Union Hospital, West Frankfort

Indiana

Harrison County Hospital, Corydon
Union City Memorial Hospital, Union City

Iowa

Ida Grove Hospital, Ida Grove
Delaware County Memorial Hospital, Manchester

Kansas

Rawlins County Hospital, Atwood
Trinity Hospital, Dodge City
Hershner Hospital, Esbon
Edwards County Hospital, Kinsley
Kearny County Hospital, Lakin
Decatur County Hospital, Oberlin
Perkins Hospital, Spearville
Sterling Community Hospital, Sterling

Kentucky

Homeplace Clinic and Hospital, Ary
Nicholas County Hospital, Carlisle
Reynolds Clinic Hospital, Hartford

Louisiana

Beauregard Memorial Baptist Hospital, De Ridder
Gonzales Hospital, Gonzales
Homer Memorial Hospital, Homer
Frank D'Ingianni Medical Center, New Orleans

Maryland

Reeves Clinic Hospital, Western Port

Massachusetts

Fuller Memorial Sanitarium, South Attleboro

Michigan

St Joseph County Hospital and Infirmary, Centerville
Veterans Administration Hospital, Iron Mountain
Schoolcraft Memorial Hospital, Manistique
Veterans Administration Hospital, Saginaw

Minnesota

Arlington Municipal Hospital, Arlington
Baudette Community Hospital, Baudette
Dr R B Johnson Hospital, Lanesboro
Mount Sinai Hospital, Minneapolis
Wheaton Community Hospital, Wheaton

Mississippi

Hardy Wilson Memorial Hospital, Hazlehurst

Missouri

Skaggs Community Hospital, Branson
Jones Clinic Hospital, Sweet Springs

Montana

Lott Hospital, Livingston

Nebraska

Community Memorial Hospital, Crawford
Crete Municipal Hospital, Crete
Veterans Administration Hospital, Grand Island
Tilden Community Hospital, Tilden

Nevada

Clark County General Hospital, Las Vegas
Pershing County General Hospital, Lovelock

New Mexico

Lincoln County Hospital, Carrizozo
Lea County Community Hospital, Hobbs

New York

Edward John Noble Hospital, Alexandria Bay
Bethany Deaconess Hospital, Brooklyn
Beverly Nursing Home, Brooklyn
Sunset Nursing-Maternity Hospital, Constableville
Edward John Noble Hospital, Gouverneur
Manhasset Medical Center Hospital, Manhasset
Wickersham Hospital, New York
Greenmont on Hudson, Ossining
Rose Hospital, Rome

North Carolina

Stanly County Hospital, Albemarle
Gardner Webb College Community Health Center, Boiling Springs
Dunn Hospital, Dunn
Good Hope Hospital, Erwin
Washington County Hospital, Plymouth
Person County Memorial Hospital, Roxboro
Halifax County Clinic Hospital, Scotland Neck
Martin General Hospital, Williamston

North Dakota

Community Memorial Hospital, Hettinger
Veterans Administration Hospital, Minot

Ohio

College Hill Hospital, Dayton
Mount St Mary Hospital, Nelsonville
Fayette County Memorial Hospital, Washington Court House

Oklahoma

Cimarron County Hospital, Boise City
Physicians and Surgeons Hospital, Holdenville
LeFlore County Memorial Hospital, Poteau
Byrne Memorial Hospital, Tulsa

Oregon

Harney County Hospital, Burns

Pennsylvania

Veterans Administration Hospital, Altoona

Rhode Island

McAlpine Memorial Hospital, Providence

South Carolina

Saunders Memorial Hospital, Florence
Edgewood Sanitarium Foundation, Orangeburg
Cannon Memorial Hospital, Pickens

South Dakota

St Michaels Hospital, Tyndall

Tennessee

Welch Clinic Hospital, Brownsville
Donalson Hospital, Fayetteville

Texas

Walter Noble Hospital, Aransas Pass
Veterans Administration Hospital, Big Springs
Panola General Hospital, Carthage
Dr Guy A Tittle Children's Hospital, Dallas
Memorial Hospital, Fort Stockton
Mauritz Memorial Jackson County Hospital Ganado
Gladewater Municipal Hospital, Gladewater
Goliad County Hospital, Goliad
Ward Bruce Hospital, Greenville
Oak Place Sanitarium, Houston
Taylor Clinic Hospital, Lubbock
Veterans Administration Hospital, Marlin
Medical and Surgical Hospital, Pasadena
Richards Clinic and Hospital, Rockdale
Snyder Hospital Clinic, Snyder
Bexar County Tuberculosis Sanatorium, Southton
Tomball Hospital, Tomball
Wolfe City Community Hospital, Wolfe City
Tyler County Memorial Hospital, Woodville

Utah

Dragerton Hospital, Dragerton

Vermont

Kerbs Memorial Hospital, St Albans

Virginia

Wytheville Hospital, Wytheville

Washington

Coulee Dam Community Hospital, Coulee Dam
Veterans' Memorial Hospital, Odessa
Seneca Summit Surgery Hospital, Seattle
Yakima Valley Memorial Hospital, Yakima

Wisconsin

Ivanhoe Sanitarium, Milwaukee
Mercy Hospital, Milwaukee

Guam

Guam Memorial Hospital, Agana

Puerto Rico

Hospital de la Concepcion, San German

CURRENT MEDICAL LITERATURE

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1939 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

A.M.A. Arch. Indust. Hygiene & Occup. Med., Chicago

2:365-486 (Oct.) 1950

Pathological and Physiological Factors Involved in Treatment of Silicosis in Coal Miners. B. Gordon and H. L. Motley.—p. 365.
Railroad Retirement Board Disability Annuities. S. C. Werch.—p. 374.
Chemical Carcinogens. J. R. Heller Jr.—p. 390.
Chronic Exposures to Air Pollutants and Acute Infectious Respiratory Diseases. A. M. Baetjer.—p. 400.
Effect of Exposure to Vapors of Tetrabromoethane (Acetylene Tetrabromide): Experimental Study. M. G. Gray.—p. 407.
Comparative Acute and Subacute Toxicities of Allethrin and Pyrethrins. C. P. Carpenter, C. S. Weil, U. C. Pozzani and H. F. Smyth Jr. —p. 420.
Chronic Oral Toxicities of Mercuri-Phenyl and Mercuric Salts. O. G. Fitzhugh, A. A. Nelson, E. P. Laug and F. M. Kunze.—p. 433.
Collection and Analysis of Solids in Urban Atmospheres. J. Cholak, L. J. Schafer and R. F. Hoffer.—p. 443.
Local and Systemic Effects Following Application of Dilute Solutions of Phenol in Water and in Camphor-Liquid Petrolatum on the Skin of Animals. W. B. Deichmann, T. Miller and J. B. Roberts.—p. 454.

86:491-648 (Oct.) 1950

Clinically the Myocardium. H. A. Christian.—p. 491.
*Aureomycin in Prevention of Bacteremia Following Tooth Extraction. O. Roth, A. L. Cavallaro, R. H. Parrott and R. Celentano.—p. 498.
Effects of Intravenous Injection of Typhoid Vaccine on Blood Leukocytes and Adrenal Cortex. M. D. Altschule, B. H. Parkhurst and E. Promisel.—p. 505.
Serum Esterified Fatty Acids with Fat Tolerance Tests in Diabetes Mellitus. E. F. Hirsch and L. Carbonaro.—p. 519.
*Adult Renal Osteitis Fibrosa with Metastatic Calcification and Hyperplasia of One Parathyroid Gland: Report of Case. E. A. Dreskin and T. A. Fox.—p. 533.
*Use of Cortisone and Adrenocorticotropic Hormone in Acute Disseminated Lupus Erythematosus. L. J. Soffer, M. F. Levitt and G. Baehr.—p. 558.
Gastroenterology: Review of Literature from July 1948 to July 1949. J. B. Kirsner, W. L. Palmer, W. E. Ricketts and others.—p. 595.

Aureomycin and Bacteremia in Tooth Extraction.—Roth and his co-workers show that dental manipulation for removal of a focus of infection in persons with damaged heart valves or congenital heart disease may cause bacteremia and precipitate subacute bacterial endocarditis. Sulfadiazine and sulfapyridine were employed prior to and following dental operations to prevent bacteremia, but these drugs were not always effective. Penicillin in oil has also been used. It reduces the occurrence of bacteremia substantially, but it occasionally causes allergic reactions. Aureomycin was used by the authors in patients who underwent tooth extraction. As the successful action of aureomycin in preventing bacteremia was yet unknown, patients with heart murmurs or patients with a history of rheumatic fever, chorea or any previously diagnosed congenital heart disease were excluded. Almost all the patients had evidence of dental infection. Every other patient received aureomycin; the alternate patients served as controls. A total of 2 Gm. of aureomycin divided in four doses was given on the day before the extraction, on the same day and on the day after. Of 25 patients who had not received any antibiotic, 14 had blood cultures positive for Streptococcus viridans immediately following tooth extraction. Among 25 patients who had received aureomycin, only one blood culture positive for Str. viridans was found. These results are important when it is realized that about 20 per cent of all cases of subacute bacterial endocarditis can be traced to recent dental manipulation. For this reason, before such an operation, every patient should be questioned and examined for valvular or congenital heart disease, and, if such a condition is found, should be given prophylactic treatment. Aureomycin is at present the drug of choice because it reduces the incidence of Str. viridans bacteremia, can be given orally, apparently does not produce drug-resistant organisms and has a relatively low toxicity.

Renal Osteitis Fibrosa.—According to Dreskin and Fox, long-standing renal disease with accompanying hyperplasia of the parathyroid glands and osteitis fibrosa is a rare syndrome, which only in recent years has been adequately described. They cite the history of a man aged 27, with a history of renal disease since childhood. He presented the clinical picture of renal insufficiency, metastatic calcifications, osteoporosis, pigmentation of the skin and a palpable mass near the lower pole of the thyroid on the left. The clinical features, except for this mass, were those of renal osteitis fibrosa generalisata. A biopsy specimen of the mass was taken, and histologic examination revealed hyperplasia of the parathyroid. The syndrome thus was complete. There was the added feature of deep reddish brown pigmentation of the skin. Following removal of the mass of hyperplastic parathyroid tissue, regression of the subcutaneous calcifications and healing of the bone lesions began despite an unchanged renal status. Laboratory studies before and after the operation showed a striking drop in serum calcium and a decided rise in alkaline phosphatase. A retrograde pyelogram showed megaloureter and hydronephrosis. Therapy included symptomatic measures, a high calcium and low phosphorus diet and administration of aluminum hydroxide. Calcium salts were given parenterally when tetanic manifestations developed. There was little change in the general status, although resorption of the subcutaneous calcium desposits occurred and evidences of bone healing appeared. The patient died in uremia after six months of observation. Autopsy confirmed the renal disease, hyperplasia of the remaining parathyroids and the healing lesions of osteitis fibrosa. The subcutaneous calcifications had completely disappeared. The authors stress that this case corresponds closely to the syndrome of chronic renal disease, decalcification of bone, parathyroid hyperplasia and metastatic calcification, as first described by Albright and his associates. This is the eighteenth such case reported in the literature. Pigmentation of the skin in this patient was striking and drew attention to the possibility of involvement of the adrenal glands. After the presence of severe renal impairment was established, it was decided that the pigmentation was on the basis of long-standing renal disease. At autopsy normal adrenal tissue was observed, lending confirmation to the latter clinical impression. Pigmentation of the skin, as in this case, occurred in more than 50 per cent of the previously reported cases of the syndrome.

Cortisone and ACTH in Disseminated Lupus Erythematosus.—Soffer and his associates investigated the influence of cortisone and of pituitary adrenocorticotropic hormone (ACTH) on 34 patients with a variety of illnesses. They report on 14 critically ill patients with exacerbations of acute disseminated lupus erythematosus. Six of the 14 patients were first treated with cortisone to establish a remission and were then treated with pituitary adrenocorticotropic hormone. Treatment in one patient was started with the pituitary hormone and later changed to cortisone. Five were treated exclusively with the pituitary hormone and two exclusively with cortisone. The initial dosage of cortisone was 150 to 200 mg. daily and that of pituitary adrenocorticotropic hormone 100 to 150 mg. The daily amount was divided into four doses. Defervescence, disappearance of the toxicity and subsidence of the joint pains were produced by both hormones. The major difference in the effects of the two agents was the time interval between the beginning of therapy and the clinical response. With cortisone, two to four days were required before the effects of therapy became evident. With the pituitary hormone, a fall in temperature to normal levels and subjective improvement were noted within 12 to 18 hours. This difference in the behavior of the two agents was also apparent after discontinuance of therapy. After the disease had been under control for several weeks, the daily dosage of both hormones was slightly reduced every few days until the minimal dosage level was established that maintained the patient in remission. This level can be more accurately gaged with the pituitary hormone because of the relatively prompt exacerbation that follows inadequate dosage. Although these hormones are capable of inducing clinical remissions, they do not effect a cure. They cause side effects. Postmortem examination of two patients who had been treated failed to show histologic changes that were different from those observed in patients with untreated lupus. The acute manifestations of the disease subsided in 11 patients. However, the characteristic lupus cells, the anemia, the thrombocytopenia and the abnormal renal findings persisted. In only one of this group could treatment temporarily be discontinued. The remaining 10 patients still require continuous treatment. Three patients died.

Surgical and Allied Diseases of Salivary Glands and Ducts. W. G. Abel III.—p. 622.
*Death Following Tonsillectomy. G. W. Taylor.—p. 642.

Results in Fenestration Operation.—Campbell evaluates the results obtained by the labyrinth fenestration operation for otosclerosis on the basis of three important factors, the degree of deafness before operation, the age of the patient and bone conduction before operation. One group composed of 16 patients with a mild preoperative loss of hearing—an average of 38 or less decibels—was compared with another group of 22 patients with a severe preoperative loss of hearing—an average of 62 or more decibels. The average improvement of hearing in the 16 mildly deaf patients was 13.2 decibels; that in the 22 severely deaf patients was 20.3 decibels. The amount of improvement obtained in the mildly deaf patients was much less than in the severely deaf patients. One group composed of 48 patients between the ages of 14 and 26 years was compared with another group of 32 patients aged 45 years or older. The average improvement in hearing in the 48 patients of the younger group was 16.7 decibels. This computation included 16 patients who were considered to have unsatisfactory results, inasmuch as they had less than 15 decibels of improvement. The average improvement in the remaining 32 successful cases was 23.5 decibels; in the 32 patients aged 45 or older, it was 16.46 decibels. This computation included nine patients who were considered to have unsatisfactory results. The average improvement in the remaining 23 successful cases was 22.1 decibels. It is significant that the hearing improvement after operation was practically the same in the two groups. A higher percentage of success was obtained in patients aged over 45 than in patients less than 25 years of age, but there was a higher percentage of patients in the younger group that obtained hearing to a practical and serviceable level.

A comparison of the postoperative results was made in two additional groups of patients, the members of the first group all having a preoperative bone conduction loss of 15 or less decibels at the 2048 frequency (essentially normal bone conduction), and those of the second group having a preoperative bone conduction loss of 30 or more decibels at the 2048 frequency. The average improvement at the 2048 frequency in the 45 patients with normal bone conduction (at the 2048 level) was 24.55 decibels and that of the 43 patients with bone conduction loss of 30 or more decibels was 21 decibels. Thus the improvement in hearing was almost as good in patients with poor bone conduction as it was in patients with normal preoperative bone conduction. Considerably reduced bone conduction at the 2048 frequency level does not necessarily indicate auditory nerve degeneration at that level and does not necessarily give a bad prognosis so far as the results of the fenestratioin operation are concerned.

Death Following Tonsillectomy.—Taylor performed a routine tonsillectomy and adenoidectomy on a Negro girl, aged 7 years. The patient was anesthetized with vinyl ether (vinethene®) and ether. The first indication of serious trouble was postoperative obstructive dyspnea due to large postnasal tampon and the heavy, thick tongue of the patient, although the degree of obstruction was not considered severe enough to warrant extra precautions. During the recovery period there was no one in constant attendance. When it was noted, five to 10 minutes after the patient had left the operating room, that respiration had ceased, almost another minute passed before the airway could be restored. Death occurred despite cardiac massage, artificial respiration and support of the circulatory system with transfusion and sympathomimetic stimulants. The basic cause of death probably was the long preliminary period of anoxia with resultant damage to the cerebral circulatory and respiratory centers. It is theoretically possible that the generalized lymphoid hyperplasia and chronic interstitial pneumonitis of this particular patient were significantly related to her death, in that her ability to recover either from the anoxia or from the strenuous resuscitative measures may have been considerably lower than normal. The effects of anoxia were too typical to consider the patient's own constitutional factors as anything of more than secondary importance. This case illustrates primarily that there should be adequate postoperative observation in order to prevent further similar episodes, especially when a postnasal pack has been inserted. The airway must be kept free and open by whatever means necessary. When accidents do occur, speed in reestablishing the airway and beginning cardiac massage is essential. While manual compression of the heart was practiced in this case, procaine hydrochloride was dropped onto the myocardium and was followed by cessation of fibrillation and resumption of cardiac action.

Control of Outbreak of Rabies.—According to Tierkel and his associates, the incidence of rabies had been at a substantial endemic level in the dog population of Memphis and Shelby counties for years. During the winter and early spring of 1948, the incidence began to reach epidemic proportions. By the end of March, cases were being reported at a rate of more than one a day. When the number of cases began to mount in December 1947, a strict dog quarantine was invoked that required that all dogs be confined or kept on a leash when out of doors. Stray dog control was adequate. On March 29, health department representatives met with the city and county commissioners, and it was recommended that an officially sponsored voluntary program be undertaken for canine vaccination. For the operation of dog vaccination clinics, the city was divided into three zones for the three days of operation, with 12 strategically located clinics held simultaneously in each zone. The rural county was similarly handled. Veterinarians supplied and administered the vaccine during the one week emergency program at a charge of $1 per dog. Standard phenolized veterinary vaccine was obtained from the usual commerical sources. Public education was effected through every available medium, the newspapers, radio, sound trucks, placards, mimeographed schedules of the clinics and the like. In the ensuing months the number of cases began to drop until the last case of animal rabies and the last human antirabic vaccine treatment were reported in July. Both city and county remained entirely free of rabies until March 10, 1949, when the first rabid dog since July 22, 1948, was picked up at the city limits. The results of this program stand as testimony of the importance of a well organized vaccination campaign.

Role of Foetal Haemoglobins in Aetiology of Jaundice of the Newborn. G. E. Delory, L. G. Israels and F. D. White.—p. 238.

Ascorbic Acid in Adipose Tissue.—Pagé and Babineau point out that they had reported previously that prolonged exposure of rats to cold causes a considerable increase in the weight of the interscapular brown fat. This hypertrophy was associated with a rise in water and in nonfat dry matter content. It was suggested that brown adipose tissue has some physiological function different from that of ordinary depot fat and that its activity is greatly increased in cold-adapted animals. Other investigators established that ascorbic acid concentration of several tissues increases in animals adapted to cold. Pagé and Babineau measured the concentration of this vitamin in brown adipose tissue. They found that at room temperature the ascorbic acid content of the brown adipose tissue is doubled when rats are fed a high fat diet. In cold-adapted rats, the brown body is considerably hypertrophied and the ascorbic acid content is from four to eight times higher than at room temperature. The weight of the perirenal fat doubled in rats exposed to cold, with little or no change in total body weight. It is concluded that cold stimulates fat metabolism and that both ascorbic acid and the brown adipose tissue are involved in the process.

Peripheral Manifestations of Visceral Carcinoma. M. P. Lipman and J. N. Tober.—p. 188.

Effect of Antibacterial Agents on Intestinal Flora.—Dearing and Heilman studied unselected, hospitalized patients who were to undergo surgical treatment for various intestinal lesions. The comparative study of the antibacterial effectiveness of aureomycin, chloramphenicol (chloromycetin®), dihydrostreptomycin, succinylsulfathiazole (sulfasuxidine®) and phthalylsulffathiazole (sulfathalidine®) on the intestinal bacterial flora in 194 patients indicated the superiority of aureomycin. The authors recommend the use of 750 mg. of aureomycin orally four times daily for three to three and a half days.

Chloramphenicol in Chronic Ulcerative Colitis.—Bercovitz reports bacteriologic studies on stool cultures and clinical observations on patients with ulcerative colitis treated with chloramphenicol (chloromycetin®). In the stool cultures, attention was given to the two major groups of organisms, Escherichia coli and streptococci. Three grams daily of chloramphenicol was found to be the most effective dosage. The stool cultures revealed marked inhibition of the growth of both E. coli and streptococci from the first to the fourteenth day of chloramphenicol therapy in 13 patients with chronic ulcerative colitis, eight normal persons and five patients in whom subtotal colectomy had been performed. In the latter group, the inhibition of bacterial growth was more pronounced in rectal mucus than in ileostomy feces. At the end of one month, 13 patients were greatly improved, three were moderately improved and the remaining eight showed no essential change. The author stresses that this is only a preliminary report. Chloramphenicol can be given repeatedly and for prolonged periods of time without evidence of toxic side reactions. Following the initial period of therapy, an interrupted schedule of treatment for relatively short periods of time is superior to constant and prolonged administration of the drug. Final clinical evaluation can be made only after a period of five years, when sufficient time has elapsed to account for spontaneous remissions.

Potassium Deficiency in Gastrointestinal Disease.—According to Smith, the body normally handles about 3 to 4 Gm. of potassium a day. During the treatment of patients with gastrointestinal disease, depletion of body potassium must be considered whenever the patient cannot take food orally, loses large quantities of gastrointestinal secretions or has a potassium diuresis as a result of intravenously administered dextrose and isotonic sodium chloride therapy or administratioin of pituitary adrenocorticotropic hormone (ACTH). Drowsiness, weakness, languor, chronic ileus with moderate distention, anorexia, nausea, edema and oliguria are significant when associated with disturbances in the electrolyte balance. In severe potassium deficiency, there may be a loss of the peripheral reflexes, dilatation of the heart and ectopic cardiac rhythms and hypotension. While an awareness of the conditions leading to potassium depletion is important, four laboratory determinations are helpful in establishing the diagnosis. These are the determination of the serum potassium and chloride levels and of the plasma carbon dioxide combining power and the electrocardiogram. Potassium deficiency may be corrected or prevented by the administration of potassium salts. Whenever possible, these salts should be given by the gastrointestinal route. Potassium deficiency rarely develops as long as food can be taken and retained. Even with a restricted diet, the use of orange juice, cereals and meat juice can supply an adequate daily intake of potassium. Potassium may also be supplied orally in tablet form as a solution of one or more potassium salts. One tablespoonful of Valentine's meat extract given four times a day will supply the equivalent of 5 to 6 Gm. of potassium chloride. When potassium salts are given parenterally, the blood reaching the heart should not contain more than 7 milliequivalents per liter. This concentration will not be exceeded when solutions containing 1 to 3 Gm. of potassium salts per liter are given at the rate of 8 to 12 cc. (120 to 180 drops) per minute. When toxic symptoms develop, the infusion of potassium salts should be discontinued immediately, administration of dextrose and isotonic sodium chloride solutions started and calcium gluconate given intravenously. The author presents four cases, two with signs of potassium deficiency, in which the correct diagnosis and treatment prevented a fatal outcome. The other two cases show that potassium deficiency can exist without great changes in the electrolyte balance and that the treatment of the deficiency can shorten convalescence.

New Concept of Venous Thrombosis.—Quick says that investigations carried out in his laboratory during the past 15 years have resulted in the formulation of a new theory of blood clotting. He considers the problem of venous thrombosis in terms of this new concept of the mechanism of coagulation. An injury to the vascular wall, even though minor, produces a rough surface to which platelets adhere. As these cells disintegrate, thrombin is produced, and the formation of a thrombus is initiated. This primary thrombus undergoes contraction and exudes a serum rich in nascent thrombin. If the circulation is sluggish, this serum will not be washed away promptly, but instead will cause the formation of a secondary thrombus on the original fibrin clot. As the new addition to the primary coagulum retracts, it gives rise to further growth of the thrombus. Clot retraction not only explains the propagation of the clot but also accounts for its nonattachment to the vessel wall except at the site of origin. Any means that diminishes or slows clot retraction should be valuable against thrombosis. The reduction of the number of circulating platelets is a theoretical means but is not feasible clinically. The reduction of the formation of thrombin is readily accomplished by heparin and by bishydroxycoumarin (dicumarol®). The correction of anemia is particularly important for the prevention of thrombosis, because the lower the cell volume the greater the retractility of the clot.

Plasma Volume and Sodium Chloride Administration.—In order to appraise the measurement of plasma volume as a guide in the administration of isotonic sodium chloride solution during the postoperative period, Aquilina and Butsch made comparative studies on two groups of 10 patients each who were subjected to partial gastrectomy for ulcer. They found that the patients who were given 11 Gm. of sodium chloride parenterally daily responded with an increased total red blood cell volume, plasma volume and amount of available protein. The patients who received no sodium chloride showed a decrease in these. The patients receiving sodium chloride postoperatively showed no ill effects. Increased plasma volume and cell volume with attendant increase in available protein evidently exert an important influence on the physiological processes of healing in the postoperative period.

Osteomyelitis Treated with Topical Detergent Antibiotic.—Grace and Bryson feel that sufficient data have now been accumulated to permit a review of the histories of 45 patients with chronic osteomyelitis treated by the technics described in earlier reports. The chronic osteomyelitis had existed for from two weeks to 51 years. Minimal surgical treatment and parenteral administration of penicillin was supplemented by local instillation of penicillin, dissolved in anionic detergent solutions, followed by primary closure of the wound. In one patient who, as the result of a compound fracture of tibia and fibula, had a persistent draining osteomyelitic sinus, an anionic detergent (tergitol,® sodium 2-methyl-7 ethyl undecyl-4 sulfate 1:1,000 aqueous solution) was used as a solvent for the penicillin (10,000 units to 1 cc.). This solution was puddled over the sinus tract after petrolatum gauze strips were placed about the opening in the form of a circular dam. Every four hours for 10 days, 5 cc. of the solution was placed in the sinus tract. The authors describe three other methods of applying antibiotics topically by means of surface active solvents. Important data, concerning bones involved, duration of osteomyelitis, causal organism, surgical and local treatments, are presented in tabular form for all 45 patients treated. The addition of a detergent to penicillin potentiates its action on staphylococci in vitro and may be instrumental in promoting contact between antibiotic and isolated bacteria in purulent or avascular areas. More than two thirds of the patients treated by the described methods had a complete arrest of the disease for periods that now extend to nearly five years of observation. Patients have been hospitalized for an average of only 10 days and are ambulatory at the termination of treatment. Thus this method offers a rapid, relatively simple therapeutic regimen and is a conservative alternative to mutilating surgery. Saucerization and other radical methods should be condemned as relics of the preantibiotic era.

Prognosis of Pneumonia in Childhood.—Holzel and Wolman review observations on 214 infants and children who were treated for pneumonia from 1946 to 1948 inclusive in two Manchester children's hospitals. The diagnosis was confirmed radiologically or by necropsy. Twenty of the children died within the first 24 hours after hospitalization. Of the remaining 194 patients, 33 died (17 per cent). This relatively high mortality was accounted for by the large number of infants less than 6 months old; there were 28 deaths among 76 infants of this age group (36 per cent). There were only five fatalities among the 118 children (4 per cent) who were more than 6 months old. There was only one death among the 77 children who were more than a year old (1.3 per cent). Five deaths occurred among 18 (27 per cent) of the infants who were treated with sulfonamides, whereas among the 36 treated with sulfonamides plus penicillin there were 11 deaths (30 per cent). Thus, no benefit resulted from the added penicillin. Attempts to lower the general mortality from pneumonia must be directed toward the treatment during the first six months of life. No prognostic significance could be attributed to the total leukocyte count or to the percentage of polymorphonuclears.

Treatment of Acute and Severe Liver Disease.—Latner says that patients with massive necrosis of the liver may linger for a number of days, whereas animals die almost immediately after hepatectomy. In some severe hepatic disorders several of the functions of the liver may remain apparently normal until death. The author developed what he terms the "intravenous liver regime," which employs two types of infusions. In the first infusion, 50 mg. of thiamin hydrochloride, 150 mg. of nicotinamide, 50 mg. of riboflavin and 0.5 Gm. of potassium chloride are added to each pint of 10 per cent dextrose in isotonic sodium chloride solution. The second infusion consists of plasma to which the vitamins alone have been added in the same concentrations as in the first infusion. A daily dosage of 1,000,000 units of penicillin is administered for 10 days. During each 24 hours, three separate pints of the first infusion are administered intravenously at six-hour intervals, and after a further six hours one pint of the second infusion is given. During this period, 300 mg. of tocopherol is administered intramuscularly in three divided doses. This treatment is continued until fluids can be administered by mouth: usually two or three days. The tocopherol should be administered by mouth as soon as possible. If there is an infection that does not respond to penicillin, a course of streptomycin can be given. The author used this treatment in two cases of infectious hepatitis with massive necrosis, two cases of massive necrosis of puerperium and one case with the hepatorenal syndrome developing after cholecystectomy. Only one death occurred in these five patients. Even the patient who died recovered from coma before death. Her death was due to a superadded infection and possibly to the fact that she did not receive the full regimen. The 80 per cent recovery rate in the five cases treated with the intravenous liver regimen contrasts strongly with the 100 per cent mortality in six patients who were treated with intravenously administered cystine. The intravenous liver regimen may also be used prophylactically after surgical operations on patients with severe liver impairment, who are notoriously bad surgical risks. The regimen has been successfully applied in two such cases.

Treatment of Severe Hypertension.—Campbell and Robertson selected eight patients with severe hypertension and papilledema for treatment with hexamethonium bromide. A dose of 100 mg. administered intramuscularly every four hours was found to cause a progressive reduction in the blood pressure in all cases. Subsequently, oral treatment was found to be satisfactory. It produced a more constant fall of the blood pressure without the fluctuations encountered when the parenteral route was used. The drug was administered in solution formed by tablets of 0.5 Gm. dissolved in 20 cc. of water. On the first day of treatment, 0.25 Gm. should be given twice, followed by 0.25 Gm. three times daily for the next two days, then 0.5 Gm. three times daily for two days, the dosage being progressively increased, until by the tenth day 0.5 Gm. is being given four to six times a day (a daily total of 2 to 3 Gm.). The drug is more effective when given before meals. The substitution of normal therapeutic measures, other than rest in bed, by oral medication with hexamethonium bromide led to an immediate fall in the blood pressure to a level that could readily be maintained by a daily total dosage of 2 to 3 Gm. The most striking results were obtained in young patients with no previous history of renal disease with symptoms of short duration and rapid progression and with no arteriosclerosis. In the presence of long-standing hypertension without a previous history of renal disease the blood pressure could be reduced to within normal limits or to levels considered desirable. Headache was abolished, papilledema regressed and vision improved in every case. All the patients are now ambulatory. The drug was withdrawn in three patients, without an immediate rise in the blood pressure;

and, although one patient required further treatment, another still had a stable normal level of pressure after eight weeks. It seems likely that continuous administration may be unnecessary.

Treatment of Obesity.—Edwards and Swyer compared the effects of thyroid, dextroamphetamine sulfate and placebos on the weight loss of obese subjects on a 1,000 calorie diet. They found that dextroamphetamine sulfate (5 mg. three times a day) had a highly significant effect in increasing weight loss when used in conjunction with a 1,000 calorie diet. Thyroid (30 mg. three times a day) had no significant effect in similar circumstances. Dextroamphetamine sulfate and thyroid had no effects on each other. The effect of dextroamphetamine sulfate persisted over the four month period of treatment, and there was no significant difference in its effects in different months. The mean weight loss per month over the four month period without dextroamphetamine sulfate therapy was 5.77 pounds (2.6 Kg.). Dextroamphetamine sulfate increased this weight loss by 2.4 pounds (1.1 Kg.) per month.

*Headache After Spinal Anaesthesia. S. R. Hunt.—p. 414.

Headache After Spinal Anesthesia.—Hunt says that the headache that often develops after spinal anesthesia may be more distressing than the operation itself. Various means have been used with some success to reduce the incidence of headaches, such as use of fine needles, lateral introduction of the bevel to produce a smaller hole and the adoption of a head-low position for 12 to 48 hours after puncture to lessen the seepage of spinal fluid. In spite of these measures, the incidence of spinal headache still remains at 20 to 30 per cent. In obstetrics, the application of a firm abdominal binder has practically abolished the condition. In analyzing his material, the author also found an amazingly low incidence in genitourinary cases. The only difference in routine care that could be found was that these patients had forced fluids. The conclusion was reached that preoperative overhydration of the patient by oral means might lead to hydremia (or provide ample reserves of fluid), which in turn would result in diminished absorption or increased production of cerebrospinal fluid. In a series of patients in which at least four pints of extra fluid—water or dextrose fruit drinks—were given from noon to night the day before the operation, the incidence of headache was low. This observation should be applicable also in diagnostic lumbar puncture.

Streptomycin in Treatment of Endocarditis Lenta.—Wollheim and Kleinfelder state that the therapeutic efficacy of penicillin in endocarditis lenta was considerably less in German clinics (20 per cent cure rate) than had been expected on the basis of Anglo-American reports. They therefore employed other antibiotics. They administered a dose of 1 Gm. of Streptomycin daily until a total of from 30 to 90 Gm. had been administered. There were no damaging effects on the vestibular nerve with this dosage. Dihydrostreptomycin, combined with an antihistamine preparation, can be used if streptomycin should produce symptoms of cutaneous allergy. Streptomycin was given to 10 patients with endocarditis lenta, one of whom died at the beginning of treatment. Three of the nine patients were cured, and no relapse occurred in eight months of observation. The remaining six patients, most of whom had abacterial forms of endocarditis, showed no improvement with streptomycin therapy, whereas treatment with penicillin produced at least temporary improvement. The authors believe that after endocarditis lenta has been diagnosed, the patient should first be treated with large doses of penicillin, at least from 30,000,000 to 180,000,000 units. If this dose does not effect improvement, as ascertainable on the basis of temperature, splenic tumor, focal nephritis, anemia and particularly the sedimentation rate of the erythrocytes, then streptomycin should be resorted to at once. Penicillin treatment can be interrupted if in patients with high fever there is an exacerbation despite daily doses of 1,600,000 units and if the absence of any signs of improvement indicates that this therapy will probably be useless. In such cases streptomycin can still be helpful, as was proved in the three cases observed by the authors.

Mode of Action of Cortisone and ACTH.—Heilmeyer and his associates treated with cortisone a patient with pulmonary and intestinal tuberculosis. The treatment resulted in a decided decrease in eosinophils and erythrocyte sedimentation rate; the temperature was stabilized, and there was a reduction in the high excretion rate of ketosteroids. An artificially induced inflammation of the skin was also much reduced by the action of cortisone. This clearly demonstrates that the antirheumatic effect of cortisone is nonspecific. It suggests that cortisone influences a regulatory process that controls various functions. In a patient with pain and swelling in the joints of fingers and hands, the disease process became activated and involved the knee and shoulder joints. A therapeutic trial with a thiosemicarbazone derivative (amithiozone) resulted in a decrease in the sedimentation rate and slight diminution in swelling and pain. Severe nausea required interruption of this treatment. When cortisone was administered several days later, the sedimentation rate alternately rose and fell, until there was a gradual decrease, which continued several days after cortisone medication had ceased. The subjective changes paralleled the sedimentation rate. The excretion of 17-ketosteroids showed the same behavior as in the first case. The authors conclude from this that the action of cortisone on rheumatic disorders is not etiotropic. They used pituitary adrenocorticotropic hormone (ACTH) in the treatment of a patient with acute leukemia and in one with chronic lymphatic leukemia. They were able in these cases to corroborate the observations of American workers with regard to the regression of these conditions. The action of the pituitary hormone on the adrenal cortex was controlled by determination of the different corticoid fractions. The results supported Selye's opinion that pituitary adrenocorticotropic hormone activates chiefly the 11-oxycorticoids, among which cortisone, which influences the lymphatic organs, is the most important. The deoxycorticoid fraction, however, has a somewhat antagonistic effect on the lymphatic organs. This corroborates the dualism of the 11-oxycorticoids and the 11-deoxycorticoids.

Malaria-Like Fever in Gastric Cancer.—Reviewing the records of 271 patients with cancer of the stomach who were treated at the Heidelberg clinic between 1940 and 1948, Hartmann noticed that some had attacks of fever. The febrile temperature in 24 could be traced to intercurrent disease, but in 20 this was not possible. These 20 patients had intermittent, malaria-like paroxysms of fever, which in some patients recurred every three or five days, in others at intervals of two to six days. Fever may be one of the first symptoms of gastric cancer. The author illustrates this with a case history. This symptom has not received the attention it deserves. Cancer of the stomach should be considered in patients whose general condition is greatly impaired, who have anemia and an increased erythrocyte sedimentation rate and who have an unexplained fever, particularly if the fever is of the intermittent or paroxysmal type. The attacks of fever may be caused by anaphylaxis-like effect of the toxins resulting from the autolysis of the proteins in the carcinoma. The occurrence of fever in carcinoma suggests an unfavorable prognosis.

*Exophthalmus from Thiouracil Therapy. G. Marañón.—p. 531.

Exophthalmos from Thiouracil Therapy.—Marañón directs attention to the occurrence of hypophysial exophthalmos and thyroid complications in thiouracil therapy of hyperthyroidism. In eight of 500 patients with hyperthyroidism treated with thiouracil or one of its derivatives, one or both of these complications occurred. Myxedema developed in four patients, in two of whom hypophysial exophthalmos became aggravated. Pronounced exophthalmos without myxedema and slight hypothyroidism developed in the other four patients. Hypophysial exophthalmos is more frequent, although more benign, after thiouracil therapy than after thyroidectomy. It can appear for the first time after thiouracil therapy, may become aggravated and progress, either alone or in association with myxedema. Treatment with thiouracil or any of its derivatives, even with small doses, is not entirely free from complications. Special care is advisable in giving thiouracil to patients with hyperthyroidism and with a tendency to edema.

*Incidence of Acute Yellow Atrophy of Liver During Last Epidemic Wave of Virus Hepatitis. (1939-1942). F. Boscardi.—p. 175.

Acute Yellow Atrophy of the Liver in Epidemics of Virus Hepatitis.—Boscardi reviews the world literature on epidemics of virus hepatitis in soldiers, from 1939 to 1948, and the records of a medical clinic in Rome concerning an epidemic in 238 civilians for the same period of time. The disease was considered benign up to 1945. Acute yellow atrophy of the liver was an extremely rare complication. From 1946 to 1948, the disease had become more acute and acute yellow atrophy of the liver much more frequent. The author believes that the virulence of the causal virus increases by the end of an epidemic of this disease, whereas immunity in the population decreases.

*Diagnosis of Intrahepatic and Extrahepatic Jaundice. Y. Edlund.—p. 1380.
Transplantation of Preserved Aortic Grafts in Dogs. T. Hiertonn and T. Borg.—p. 1387.
*Transitional Endometrium. V. Oram.—p. 1389.
Pneumococcus Types in Ulcus Serpens Corneae. Y. Barkman.—p. 1391.
Tuberculosis of Lymph Nodes with Leukemoid Reaction. B. Sørensen. p. 1394.

Diagnosis of Intrahepatic and Extrahepatic Jaundice.—Edlund asserts that the most important requirement for a correct diagnosis of intrahepatic and extrahepatic jaundice is a detailed case history. Laboratory tests serve as a supplement to the clinical observations. Determination of the bile pigment metabolism and quantitative determination of the bilirubin content in the serum are recommended. Pronounced increase in the bilirubin values points mostly to intrahepatic jaundice or possibly a malignant obstruction. Benign obstruction usually gives moderate hyperbilirubinemia and, significantly, intermittent jaundice. Simultaneous determination of the urobilin in urine and feces is useful. In intrahepatic jaundice there is a definite increase of urobilin in the urine, with normal or somewhat reduced urobilin in the feces. Malignant obstruction is usually associated with reduced urobilinogen content in the urine and acholic feces. In benign obstruction, in which there is usually partial obstruction of the common duct, there are generally no typical changes in urobilin excretion in urine and feces. The citric acid test and phosphatase determination in the urine, together with the thymol test, must be considered routine procedures. In intrahepatic jaundice the citric acid values are generally high, the phosphatase values normal and the results of the thymol test positive, while normal citric acid values, elevated phosphatase values and negative results of the thymol test point to extrahepatic jaundice. In jaundice of long standing (suspected cirrhosis), determination of the total serum albumin and the albumin-globulin quotient as well as the Takata-Ara test may be indicated, cirrhosis is as a rule marked by reduced albumin content and disturbance in the albumin-globulin quotient and positive Takata-Ara reaction Needle biopsy of the liver may be performed if the diagnosis continues uncertain, although the results are not always reliable As a last resort, laparotomy is permissible but even with careful preoperative treatment a simple laparotomy may have a fatal outcome

Transitional Endometrium—Oram says that the transitional phase between proliferation and secretion, which he calls transitional endometrium has been found at times when, according to simple computation the secretory phase would be expected Study of 224 cases of typical transitional endometrium indicates that a deficient cyclic development of the endometrium is probably due to disturbances in the hormonal balance Clinically, the picture is seen most often in the age groups 15-25 and 35-45 Most cases are characterized by long continued metrorrhagia, pronounced or weak, in some cases scanty hemorrhages occur at longer intervals In about half the cases the disorder occurs from six months to a year after childbirth and/or abortion, in the other half there is no evident cause In 75 per cent of the cases there is cystic degeneration of the ovaries or combined uterine fibroma and cystic degeneration The symptomatology otherwise consists of features that are probably dyshormonal Examination of 158 patients by the chromic acid-toluidine blue staining method showed that 80 to 90 per cent were in a cycle stage corresponding to the early or late proliferation stage In 70 per cent, there were minimum and pronounced disturbances in secretion, the most definite disturbances being in the patients with cystic degeneration of the ovaries, which is thought to emphasize the hormonal genesis Hormonal treatment of a number of patients with transitional endometrium with considerable disturbances in secretion resulted in improvement in about half

*Influence of Streptomycin on Skin Reactivity to Tuberculin Experimental and Clinical Study R I Vaccarezza A Cetrangolo and R H Stupenengo.—p 1299

Streptomycin and Skin Reactivity to Tuberculin.—Vaccarezza and collaborators studied the skin reaction in guinea pigs inoculated with virulent tubercle bacilli and then treated with streptomycin The reactivity of the skin of guinea pigs treated with streptomycin greatly diminished as compared with that of the controls The earlier the administration of streptomycin after inoculation, the later the appearance of tuberculin sensitivity The reactivity of the skin to tuberculin returned to normal after discontinuation of streptomycin The reactivity of the skin to tuberculin was determined in 54 patients with pulmonary tuberculosis before, during and after streptomycin therapy The skin reactivity to tuberculin diminished in the course of streptomycin therapy in all cases except in two cases of miliary tuberculosis, in which it increased The changes in reactivity were independent of the course of pulmonary tuberculosis The reactivity returned to normal after discontinuation of the drug Thirty-two persons with a positive tuberculin skin reaction and 13 patients with pulmonary tuberculosis responded with greatly diminished skin reaction when the test was made with a mixture of tuberculin plus streptomycin Streptomycin in the blood as well as in vitro neutralizes the antigenic power of tuberculin

*Problem of Relapses in Typhoid and Paratyphoid Fever in Patients Treated with Chloramphenicol (Chloromycetin) A Laporte, D Fritel G Ricordeau and C Betourne —p 989
Penicillin Treatment of Adult Patients with Infectious Mononucleosis P Michon —p 990
Coronary Attack During Mitral Stenosis G Gelin J de Brux and G Harriague —p 992

Relapses in Typhoid and Paratyphoid Treated with Chloramphenicol—Laporte and co workers emphasize that although chloramphenicol (chloromycetin®) is effective in typhoid and paratyphoid, it does not prevent relapses They advance the concept that chloramphenicol does not easily reach the bacteria within the lymph nodes and does not sterilize them completely, because of a poor blood supply of certain lymphatic areas The survival of the bacteria within the lymph nodes causes the relapses To prevent these relapses, chloramphenicol therapy was combined in 23 cases of typhoid and in 15 cases of paratyphoid with vaccine therapy or pyretotherapy A total dose of 21 to 30 Gm of chloramphenicol was administered over 12 to 14 days to eight patients and in the course of eight to 10 days to 30 patients Of the 38 patients, 13 were given subcutaneous injections of T A B vaccine (against typhoid, paratyphoid A and paratyphoid B), 10 patients were given blood transfusions and 15 patients were given intravenous injections of antigonococcic vaccine Relapses occurred in only two of the 38 patients (5 per cent) instead of 15 to 20 per cent, as when chloramphenicol was given alone The therapeutic effect produced by any of the three methods employed exerts a general and a local effect by reaching the bacteria within the lymph nodes and thus reduces the incidence of relapses

*Frequency of Tuberculosis of Spleen in Pulmonary Tuberculosis of Adults Study of 200 necropsies H Rodriguez Castells —p 300

Tuberculosis of Spleen in Pulmonary Tuberculosis—Rodriguez Castells reports on the frequency of tuberculosis in the spleen among 200 necropsies on patients who died from advanced pulmonary tuberculosis Tuberculosis of the spleen was present in 75 instances (37 5 per cent) It was of the miliary type in 73 cases and caseous in two There was a frequency of tuberculosis of the spleen of 100 per cent in miliary pulmonary tuberculosis, followed in order of frequency by chronic pulmonary caseous types and by acute pulmonary cavitation Tuberculous lesions were not present in the spleens of patients who died suddenly from hemoptysis or as the result of an operation The author believes that tuberculosis of the spleen is due to hematogenous spread of tuberculosis through the splenic artery Tuberculous bacillemia may occur at any stage of pulmonary tuberculosis However tuberculosis of the spleen develops only when tuberculous bacillemia occurs at a time when the organic defenses are diminished and the tissues are susceptible Acquired immunity does not prevent its development The type of reaction of the spleen depends on the condition of organic allergy when bacillemia occurs

More Recent Antibiotics Aiding the Surgeon G Neff —p 1001
*Treatment of Bang's Disease with Aureomycin E Stoffel —p 1005
Insulin Myocardosis K Akert —p 1010

Aureomycin in Brucellosis—Stoffel administered aureomycin to 12 men and three women with brucellosis Eleven patients had an acute episode of fever while four had an afebrile interval Seven patients had severe organic changes, with osteomyelitis and spondylitis in four lung infiltrates in two strumitis in one and severe hepatopathy associated with cachexia and arthritis in one A total of 2 Gm of aureomycin was administered daily by mouth in doses of 0 5 Gm every six hours, with a total dose of 14 to 30 Gm Defervescence occurred in one to four days, followed by subjective and objective improvement There was a recurrence in the patient with hepatosplenomegaly arthritis, lung infiltrate and cachexia, but complete recovery resulted from three courses of 26 27 and 26 Gm of aureomycin respectively i e, from a total dose of 79 Gm Rapid healing of the osteomyelitic and spondylitic lesions and of strumitis was spectacular in other patients Eight patients responded well to aureomycin, while previous treatment with an aminopyrine preparation (causyth®), intravenously administered vaccine sulfonamide compounds or streptomycin had failed Side reactions consisted of gastrointestinal disturbances that did not require discontinuation of aureomycin and that subsided after treatment was terminated Pruritus and stomatitis occurred in one instance Follow-up of the patients for three to eight months showed no recurrences, except for the one patient mentioned before Aureomycin therapy is the method of choice for the treatment of brucellosis

BOOK NOTICES

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

Recent Progress in Hormone Research: The Proceedings of the Laurentian Hormone Conference. Volume V. Edited by Gregory Pincus. Committee on Arrangements: R. W. Bates, and others. Cloth. $8.80. Pp. 537, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1950.

The proceedings of the annual Laurentian Hormone Conference have established themselves as one of the most authoritative sources of information on the experimental and clinical aspects of endocrinology available today. The report of the fifth conference proves to be no exception.

Touching on a borderline aspect of endocrinology, the paper by Tainter and Luduena on sympathetic hormonal transmission and the discussion by Gerard on the acetylcholine system in neural function will be of interest to physiologists and pharmacologists as well as to endocrinologists. Tainter's paper is largely a review of present concepts of sympathetic nerve transmission, and little new information is added. It is valuable, however, because it attempts to assemble all the known facts regarding the humoral mediation of nerve impulses in this system and to present a unified hypothesis to account for these facts. The discussions by Bacq, Bülbring and Raab are valuable additions to the paper. The paper by Gerard is an excellent companion to that of Tainter and Luduena. Four papers on ovarian physiology and function comprise the second portion of these proceedings. Reynolds advances a fresh viewpoint on ovarian physiology in his review of his painstaking investigations of the vasculature of the ovary and the anatomic and dynamic changes that take place with changes in functional state and in disease. Parkes presents an admirably written review of investigations on the androgenic activity of the ovary, which is a mine of information on species variability. This subject, unfortunately, is still in an unsettled state because of failure to isolate from the ovary substances having an androgenic effect. Paschkis and Rakoff give a logical and rather detailed review of the estrogenic hormones from the standpoint of their origin and pharmacologic and physiological effects. Finally, Bradbury, Brown and Gray discuss the maintenance of the corpus luteum from the standpoint of comparative physiology. The physiological actions of progesterone and the significance of pregnanediol excretion receive much attention.

At this conference, consideration of the pituitary gland revolved around the factors affecting its control rather than on the physiological actions of the pituitary hormones themselves. Greep and Jones discuss the effects of estrogens, androgens and adrenal hormones on pituitary function. Their work, which was largely quantitative, throws light on the question of what may be considered as "physiological" quantities of these hormones. Noble, Plunkett and Taylor present some preliminary studies on the modification of action of pituitary hormones by lithosperm. A regular feature of the Laurentian Hormone Conferences are the papers on steroid chemistry. An interesting paper by Grant and Beall details the methods used to isolate the estrogen conjugates which occur naturally and the preparation of synthetic sulfates of natural estrogens. A brief discussion of the synthesis of radioactive estrone sulfate is also given, and Engel's paper on the chemical estimation of steroid hormone metabolites marks a notable advance in this field. The problem of separation of steroids from mixtures has always been a troublesome one, but, by the application of the Craig countercurrent distribution technic, Engel offers a simple and reliable tool which may well prove to be a key to unlock the door to a better understanding of steroid metabolism.

A discussion of hormones and tumors is contained in two papers, one by Woolley on experimental adrenal cortex tumors, in which the genetic and endocrine factors are well discussed, and the other by Soffer and associates, dealing with clinical endocrinology, with a discussion of the virilizing syndrome in man. The congenital, prepuberal and adult types of adrenocortical hyperfunction are discussed, and the relation of pituitary function to adrenal hyperplasia is elucidated by metabolic studies. Certain aspects of hormonal mechanisms are outlined in two papers. Sutherland discusses the hyperglycemic factor of the pancreas and its relation to epinephrine in glycogenolysis. The evidence appears to indicate that the hyperglycemic factor is a protein and may be a second pancreatic hormone. It acts like epinephrine in that it accelerates the breakdown of glycogen in the liver. The most intriguing and perhaps the most fundamental work in endocrine mechanisms was presented by Meyer and McShan, who reviewed their investigations on hormone-enzyme reactions. Two aspects of their work were presented: the changes in tissue enzyme in normal and hormone-deficient animals and the in vitro effect of estrogens on oxidative enzymes. The changes in enzyme concentrations are shown to occur as a result both of changing hormone levels and of nonhormonal factors. This complicates the interpretation of results, but, by correlation of changes in organ function, tissue enzymes and hormonal levels, it appears that some hormones may act on enzyme systems to effect shifts of metabolism to alternative pathways with consequent shifts in morphological and functional patterns.

As always, the discussions reproduced at the end of each paper add greatly to the formal presentation. The arrangement and editing of these proceedings is a testimony to the perspicacity of the committee on arrangements of the conference and especially to the editor of the proceedings, Dr. Pincus.

Our Rejected Children. By Albert Deutsch. Cloth. $3. Pp. 292. Little, Brown and Company, 34 Beacon St., Boston 6, 1950.

This is an arresting and sobering book. Documented as it is, there is no reason to doubt the existence of the deplorable and shocking conditions which exist in the so-called training schools or reform schools maintained by the various states for the so-called care of delinquent children. The author charges that institutional maintenance and the external appearance of buildings and grounds are emphasized above education for the unfortunate inmates. He states that in many instances the dairy herd is treated better than are the children. Food is often poor and sometimes repulsive. Cruel treatment, in the nature of both physical violence and psychological torment, are common practice even in institutions where these things are officially prohibited.. The author considers the worst aspect of these institutions to be the deadly, destructive monotony to which the inmates are subjected, giving them a sense of hopelessness and frustration. The examples of laziness, drunkenness, cruelty and immorality which are constantly set before the inmates by low grade supervisory personnel can, in the author's judgment, have no influence except to make criminals, not only of delinquents, but also of nondelinquents who are indiscriminately placed with delinquents for custodial care.

The author is careful to designate the good as well as the bad, though unfortunately the latter predominates. He gives due credit to persons who, despite the system, endeavor to do the best they can for their unfortunate charges. He lays the principal blame on the state legislatures which fail to provide adequate appropriations and thus perpetuate the system whereby institutional personnel can be recruited only from untrained and often degenerate personnel. Low salaries, lack of incentive and political insecurity do not attract the right type of person. The author further believes that most institutions are too large; he presents 12 constructive suggestions for improving conditions.

In the second part of the book he deals with courts, jails and detention homes in their relation to child "crime" and delinquency, and here he paints an even darker picture, if possible, than with regard to the training schools He discounts the idea that comic books, radio, television or crime literature, in and of themselves, are causes of juvenile misbehavior, but he does offer and ably defend the thesis that our entire culture exalts the criminal and condones crime We make heroes of successful criminals, and mystery thrillers involving murder, robbery and sex constitute our most popular escape diversion We consider it smart rather than criminal to cheat the income tax, evade rationing regulations, put over slick deals and violate regulations made for the common good, such as those for speed and traffic control and fire prevention While he does not believe that the parents of a bad child are necessarily more than partially responsible for delinquency, he does indict our entire social fabric, and he makes a compelling and thought-provoking job of it While this is a shocking book, it is not merely a job of muckraking It is a serious, factual and eminently fair presentation of the author's observations and experiences, together with constructive suggestions for improvement Thoughtful citizens, especially physicians, will find in it much food for thought and strong stimulus toward action

Essentials of Medicine. The Basis of Nursing Care By Charles Phillips Emerson Jr, A B, M D, Associate Professor of Medicine, Boston University School of Medicine, Boston, and Jane Elizabeth Taylor, R N, B S, M ED Sixteenth edition Cloth $4 Pp 815, with 191 illustrations J B Lippincott Company 227 231 S 6th St, Philadelphia 5, Aldine House, 10-13 Bedford St, London, W C 2, 2083 Guy St, Montreal, 1950

This book has always been a rather popular textbook, particularly for nurses In this edition the authors have made certain revisions, which include the expansion of medical knowledge and some recent therapeutic developments In spite of the fact that it is declared to be a compendium of the practice of internal medicine, it could not be regarded as a good textbook on this subject. This is an attempt to put a system of medicine within the covers of a book, and this obviously is most difficult to do.

The organization of the book is good The material is presented in 12 units The first unit consists of an introduction to nursing care, followed by sections on the respiratory, circulatory, digestive and renal systems One unit is devoted to the integumentary system Then follow units on allergic conditions, the endocrine glands and metabolism and the nervous, musculoskeletal and reproductive systems The last unit is devoted to communicable diseases The book is well illustrated, and the illustrations are reasonably accurate, but many could stand extensive revisions and deletions

Those parts of the text which deal with the use of antibiotic and chemotherapeutic agents in the treatment of communicable diseases contain a number of inaccurate statements One glaring example is the recommendation of administration of aureomycin by the intramuscular route, a practice which should not be recommended to either nurses or physicians Each unit contains selected references, which in general are good This book compares favorably with any similar book designed for the same purpose

Inventions Patents and Monopoly By Peter Meinhardt With a Foreword by James Mould K C Second edition Cloth 30s Pp 320 Stevens & Sons Ltd 119 120 Chancery Lane London, W C 2, 1950

This edition of this interesting study of British patent law and practice was necessitated by the numerous and important changes in the law introduced by the Patents Act, 1949, the Monopolies and Restrictive Practices Act, 1948, and the Development of Inventions Act, 1948 The book serves as an excellent, up to-date reference on the subject The author discusses the many details of patent law and practice, with numerous comparisons of the British law with that of other countries, particularly the United States The monopoly referred to in the title relates to the British attempt to curtail the abuses of patent monopoly Unlike our law, English law has set up safeguards to deal with the wrongful suppression of patented inventions, the restriction of the use of inventions of food and medicines, the charging of excessive prices for patented articles and the wrongful refusal to grant licenses on reasonable terms The author has succeeded in writing a readable book, eliminating intricate or moot legal points It should prove useful to inventors and businessmen as well as lawyers

Regional Dermatologic Diagnosis A Practical System of Dermatology for the Non-Specialist By Ervin Epstein M D Consultant in Dermatology and Syphilology to the Oakland Area Veterans Hospital Oakland, California Cloth $6 Pp 328, with 148 illustrations Lea & Febiger, 600 S Washington Sq, Philadelphia 6, 1950

The author of this modest volume is a well qualified dermatologist He has written this book to prepare a regional guide of diseases of the skin for the general practitioner and medical student It is not intended as a reference book for dermatologists

The author believes that a practical system of dermatology for the general practitioner must be based on a single, easily recognized, reasonably constant characteristic In this case, one of the most constant characteristics of a skin disease, namely the location of the eruption, has been employed as the foundation stone for accurate diagnosis The book is arranged to take advantage of this feature Each chapter is divided into sections headed, e g, Inflammations, Granulomas, Tumors and Atrophies Under each heading, the conditions are arranged roughly in the order of frequency of occurrence The rarities are dismissed with brief mention at or near the end of each section The subject matter is covered in comparatively simple fashion, as is essential in a book of this type written expressly for the general practitioner Therapy is mentioned briefly under the more important dermatoses At the end of each chapter, a table lists the more important diseases and the important features of each There are three appendixes which briefly describe the common locations of the most frequently encountered skin diseases, the principles of local therapy and the more important cutaneous manifestations of systemic disease Unfortunately, the author has given no bibliography and no reference sources. These would have been of considerable value to the practitioner desiring further information on specific subjects The book is well printed on a good quality of paper, abundantly illustrated with good photographs and substantially bound The author's style is simple yet adequate Discussions of controversial topics are brief, and the opinions presented are primarily those of the writer The book should be of some value to the physician in general practice

Diagnosis & Treatment of Tumors of the Head and Neck (Not Including the Central Nervous System) By Grant E Ward M D, D Sc, F A C S, and James W Hendrick M D M S Cloth $15 Pp 832, with 646 illustrations The Williams & Wilkins Company, Mount Royal and Guilford Aves, Baltimore 2 1950

Drs Ward and Hendrick have drawn on their vast and rich experience with malignancies to present a most valuable book to the profession They have not hesitated to enlist the aid of anatomists, otolaryngologists, ophthalmologists, radiologists, plastic surgeons and dental surgeons, where the particular knowledge of these specialists would enhance the value of this book The material is presented in a clear and lucid manner, and is well illustrated by numerous, excellent diagrams and photographs Interestingly presented from an important standpoint is the relation between embryology and clinical findings There is no verbosity in the text There are a number of photomicrographs that are not as clear as they might be It is quite evident from the extensive bibliography that a thorough survey was made of the literature The material is exceptionally well arranged and the lesions of the various anatomic parts are discussed in chapters under their own heading In the section on tumors and diseases of the salivary glands, sialography is rather well discussed with reference to the parotid gland, but no mention is made of the submandibular gland, nor are there any illustrations of it It would be well to include this in future editions. There is a succinct and excellent discussion on the use of nitrogen mustard therapy of lymphomas.

If a defect results from removal of a benign tumor of the mandible, it is the consensus that reconstruction should begin in the operating room at the time of the primary surgery rather than after a minimum period of two weeks as suggested in the book.

There are many excellent photographs of detailed procedures and appliances. The description of both the operations and the appliances would be enhanced by diagrams. The style makes for interesting reading. One is impressed with the fact that the authors speak with convictions arising from a tremendous clinical experience and thorough analysis of symptoms and observations and various methods of treatment. This book can well be used as a textbook or reference book and should be of great value to anyone interested in tumors of the head and neck. It is highly recommended.

Tratado de patología y clínica médicas. Dirigido por el Prof. Agustín Pedro-Pons, catedrático de patología y clínica médicas en la Universidad de Barcelona. Tomo VI: Enfermedades infecciosas, intoxicaciones, enfermedades profesionales y por agentes físicos. Por Agustín Pedro-Pons, Pedro Farreras Valentí, profesor adjunto de patología y clínica médicas en la Universidad de Barcelona, y Juan Surós Forns, jefe de Clínica de la cátedra de patología médica del Prof. A. Pedro-Pons, Barcelona. Paper. Pp. 975, with 364 illustrations. Salvat Editores, S. A., 41-49 Calle de Mallorca, Barcelona, Spain; Calle Lavalle Nº. 371, Buenos Aires, 1950.

This volume concerns infectious diseases, intoxication, occupational diseases and diseases caused by physical agents. The language is clear and concise. This is a large volume printed in rather small type. The field covered is extensive, and the description of the diseases is methodical and detailed. The first part of the book contains general concepts on infections, parasitosis, contagion, diagnosis, epidemiology, prophylaxis and treatment of infections. The author discusses diseases produced by bacteria, viruses, rickettsias, Bartonella, spirochetes, protozoa, helminths, arthropoda and mushrooms. The second part contains a discussion of intoxication, occupational diseases and diseases caused by physical agents. This is one of the most thorough treatments of this subject. It should be of great value to those Americans with a knowledge of Spanish, particularly to those interested in the so-called tropical diseases. The book contains numerous illustrations in color and in black and white, with many charts and graphs that simplify the discussions. There is no bibliography.

Handbook of Physiology & Biochemistry. Originally "Kirkes" and Later "Halliburton's." By R. J. S. McDowall, M.D., D.Sc., Professor of Physiology, University of London, King's College. Fortieth (centenary) edition. Cloth. $7. Pp. 767, with 315 illustrations. The Blakiston Company (Division of Doubleday & Company, Inc.), 1012 Walnut St., Philadelphia 5; John Murray, 50a Albemarle St., London W.1, 1950.

It is indeed rare to find a textbook with a new edition 100 years after its initial publication. This book first appeared in 1848 under the authorship of William Senhouse Kirkes, of St. Bartholomew's Hospital, London, England. It became known as "Kirkes' Physiology" and underwent 13 revisions until, in 1896, Professor Halliburton undertook the task of revision, and 17 editions appeared between that time and 1928. During this period, the book was known as "Halliburton's Physiology." In 1928, Professor McDowall undertook the task of revision, and in 1937 "Biochemistry" was added to the title. The present edition constitutes the 40th revision since 1848.

This book is designed primarily for medical students. Although "Biochemistry" appears in the title, it is not an adequate textbook on this subject. Rather, it is a textbook on physiology written from a biochemical viewpoint. Thus, mechanical or physical concepts in physiology are subordinated to the chemical aspects. The introduction to the subject in the opening chapter lacks completeness. Physiology is the basis of medicine, and for this reason it is important that definitions and basic concepts be presented in detail. In this book, the student is rushed too rapidly into the details of the subject, and he will find himself among the trees before he has had a chance to look at the forest.

Another defect, common to almost all textbooks on physiology, is the omission of any adequate discussion of physiological psychology. A chapter on this subject would help orient the student for later studies in psychiatry. On the credit side, the discussions of metabolism, secretion and digestion are good. There is an excellent chapter on physiological optics, a subject often slighted in physiology textbooks.

This book is not outstanding. It lacks the meticulous attention to detail and the evenness of those editions of Howell's physiology published during the latter years of Howell's life, but it can be recommended as one of the better current textbooks on physiology.

Practical Gynecology. By Walter J. Reich, M.D., F.A.C.S., F.I.C.S., Attending Gynecologist, Cook County Hospital, Chicago, and Mitchell J. Nechtow, M.D., Associate Attending Gynecologist, Cook County Hospital, Chicago. Cloth. $10. Pp. 449, with 187 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1950.

In line with the increased attention now being focused on the mind in all branches of medicine, the opening chapter of this book concerns psychosomatics in gynecology. From this the authors proceed with chapters which deal with history taking, physical examination, laboratory tests, endocrinology, infections, neoplasms, infertility and other subjects. In the preface, the authors say they fervently hope the Papanicolaou smear test will become as routine as the Wassermann test but that this utopia is a long way off. In the chapter dealing with dysmenorrhea, the authors advocate many proprietary drugs, some simple but others as strong as 100 mg. of meperidine (demerol®) hydrochloride. Emphasis is placed by the authors and the publishers on the fact that this book deals with office gynecology, but diagnostic curettage for carcinoma should be a hospital procedure, because the scraping must be a thorough one. Likewise perineotomy and repair for vaginismus must be done in a hospital, as judged by the authors' illustrations. Few gynecologists now use instrumental dilators to overcome vaginismus as illustrated and described. Likewise, not many gynecologists favor preovulatory dilatation of the cervical canal with the hope of mechanically enlarging cervical openings or breaking up cicatrization. Contrary to the view of the authors, semen should not be deposited in the uterine cavity in cases of artificial insemination even when the husband's semen is used because of the danger of infection. The illustration shows the deposition of semen in the cervical canal, and, while this is proper in cases in which the husband's semen is used, it will suffice to deposit a donor's semen against the external os of the cervix. In spite of the few minor criticisms, the book should be helpful. It is well written and practical because it is based on the authors' extensive experience. The illustrations are beautiful and instructive, although a few photographs are indistinct. The paper is sturdy, and the book is well bound.

Massage reflektorischer Zonen im Bindegewebe bei rheumatischen und inneren Erkrankenungen. Von Dr. Hede Leube, Leiterin der Krankengymnastikschule der Universität Freiburg i. Br., und Elisabeth Dicke. Mit einem Geleitwort von Prof. Dr. med. W. Kohlrausch. Fourth edition. Boards. 4.50 marks. Pp. 84, with 27 illustrations. Gustav Fischer, Villengang 2, Jena 15b, 1950.

The authors of this book are convinced that massage has especially favorable effects in certain rheumatic and internal diseases if it is concentrated on certain areas of the trunk, designated as reflexogenic areas. According to the foreword, the distinctive feature of this work is the discovery that primary disease in a given viscus is accompanied by palpable changes in the skin, the tela subcutanea and the interstitial connective tissues. The areas of correspondence are determined by known neuroanatomic relations. They have a diagnostic value, and, whenever it has been possible (by using the technics described in this book) to restore the normal degree of turgor or tension in the superficial area, the trouble in the corresponding visceral area has vanished.

These claims are rationalized by the authors in terms of undeniable facts of anatomy; the claims are limited, moreover, to *functional* disorders that can be explained in terms of the involuntary musculature of blood vessels and sphincters. For this reason, it must be admitted that the authors have at least made their idea sound plausible. They have also presented it succinctly and readably. For instance, the section on liver and bile passages (pages 75 to 78) is a concrete application of the general idea to the particular case. It should, therefore, not be difficult to obtain well controlled clinical evidence for or against the effectiveness of the recommended procedures in a series of carefully made diagnoses, say, of biliary dyskinesia. It is to be hoped that such evidence will soon be supplied.

Medical Entomology, with Special Reference to the Health and Well-Being of Man and Animals. By William B. Herms, Sc.D. Fourth edition. Based on the Book Known as Medical and Veterinary Entomology. Cloth. $9. Pp. 613, with 191 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1950.

This edition of this widely employed textbook of entomology lives up to its deserved reputation as a systematic presentation of that branch of applied biology. The shortening of the main title to "Medical Entomology" from "Medical and Veterinary Entomology" used in earlier editions should not be construed as a lessening in consideration of the animal aspects of the science. Indeed, the author continues to emphasize the importance of the relation of all forms of life to insect vectórs in the transmission of disease, so that essential, fundamental concepts are provided for the student. The book retains the original scheme of presenting details of certain experiments to illustrate the methods of investigation that can be employed to expand knowledge of the subject.

The new edition has been brought as nearly up to date as possible without altering the general plan of the contents. The free use of quotations and previously collated data is partly cumulative from previous editions and provides an abundance of historical information. The scope of the book, however, is that of a manual rather than an exhaustive treatise. The typography is clear without excessive use of boldface, and the illustrations, many diagrammatic, are adequately labeled. Each section is followed by a list of references suited more for collateral reading than for documentation. The index is unusually thorough and accurate. A typographic error, "typhiod," occurs in a citation on page 19, but on the whole the proofreading appears to have been carefully done. Teachers and field workers alike will appreciate this authoritative guide to the practical application of entomology.

Proceedings First National Conference on Cardiovascular Diseases 1950. Published by the American Heart Association in Cooperation with the National Heart Institute, U. S. Public Health Service, Federal Security Agency. Paper. $1.75. Pp. 259. The American Heart Association, 1775 Broadway, New York 19, 1950.

On Jan. 18-20, 1950, the first national conference on cardiovascular diseases was held in Washington, D. C., under the auspices of the American Heart Association and the National Heart Institute of the Public Health Service. This conference brought together 196 distinguished professional and lay experts to discuss what is known now about cardiovascular disease and how this knowledge can be applied to prevention and cure. Except for the addresses of several speakers on the opening day of the conference, the book is largely made up of reports of the various sections into which the conference was divided. These reports, covering all phases of the cardiac problem from medical research to sociology and biostatistics, form stimulating reading. The reports are generally concise and to the point and cover (frequently in outline form) what is known about the subject, deficiencies in knowledge and what measures should be taken to close the gaps in knowledge.

Kinesiology. By Laurence E. Morehouse, Ph.D., Associate Professor of Physical Education, The University of Southern California, Los Angeles, and John M. Cooper, Ed.D., Associate Professor of Physical Education, The University of Southern California, Los Angeles. Cloth. $4.50. Pp. 435, with 97 illustrations. The C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1950.

This volume, intended primarily for the physical educator, confines itself chiefly to consideration of the skilful use of the musculature and lever systems of the body in physical activity. Since the book is concerned with the activity of normal, healthy persons, pathological conditions are touched on only incidentally. After a preliminary discussion of structure and function, including the mechanics of movement, major emphasis is given to the application, of kinesiological principles to sports and games and the fundamental activities basic to them, such as walking, running, jumping, falling, lifting and carrying, hanging and swinging, throwing, striking and catching. Special sections on static and dynamic posture, swimming and indicative and deceptive movements in sports provide insight into the somewhat unique kinesiological problems involved. The text is unusual in its practical and functional approach, which has been achieved without loss of scientific accuracy. Liberal use of example and illustration make for a clear presentation. One feels that today's student will have a happier time and a clearer understanding of kinesiology than his earlier counterpart, who was concerned mainly with memorization of muscle origins, insertions and actions, with little or no reference to practical application.

Oral and Facial Cancer. By Bernard G. Sarnat, M.D., F.A.C.S., Professor and Head of the Department of Oral and Maxillofacial Surgery, College of Dentistry, University of Illinois, Chicago, and Isaac Schour, D.D.S., Ph.D., Sc.D., Coordinator of Cancer Instruction, Professor and Head of the Department of Histology and Associate Dean in Charge of Postgraduate Studies, University of Illinois College of Dentistry, Chicago. With a Foreword by Andrew C. Ivy, Ph.D., M.D., D.Sc., Vice-President in Charge of Chicago Professional Colleges, University of Illinois, Chicago. Cloth. $6. Pp. 300, with 120 illustrations. The Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1950.

A scientific book should be either a textbook, a reference book or a manual. The first 43 pages of this book deal with generalities that are interesting. However, in a highly specialized book such as the title indicates, it must be assumed that the person using this book for reference has a basic understanding of the cancer problem. For the student's use it is not detailed enough. The impression is given that squamous cell carcinoma of the skin is predominantly produced by the actinic rays of the sun. Carcinoma of the various intraoral regions is treated superficially and wholly inadequately. The case history reports are incomplete and lack necessary details. The greater part of the various regional chapters (which in themselves are much too brief) concerns anatomy rather than clinical considerations. There is also a separate chapter on anatomy and physiology of the face and oral cavity. This would be better suited to a book or treatise on surgery of the face and mouth, rather than to a highly specialized book such as this. The physiology of bone fractures does not belong in a book of this nature. Leukemia and Hodgkin's disease are primarily blood dyscrasias and not neoplasms, as the authors lead one to believe. Several sets of questions are included for students. The arrangement of the material in this book is too haphazard and confusing; for example, the chapter on oral and facial examination is beyond the middle of the book, after the regional clinical considerations have been discussed. The statement is made that "about 40 per cent of cancers of the head and neck and 60 per cent of cancers of the gingivae are first seen by the dentist." There is no reference regarding statistics to prove this statement. The appendix is a repetition in summary of the text. The format of the book makes it very readable. The excellent photographs and diagrams add interest; however, this book is neither a reference book, a textbook nor a manual.

The Pathology of Internal Diseases. By William Boyd, M.D., M.R.C.P., F.R.C.P., Professor of Pathology and Bacteriology in the University of Toronto, Toronto. Fifth edition. Cloth. $11. Pp. 866, with 402 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1950.

Few authors possess the gift for presentation of medical problems in a lucid, understandable manner. Dr. Boyd has succeeded in presenting this information to the reader in a manner that is understandable and at the same time interesting. This is of particular importance when such information is written for the medical student or the busy practitioner.

Changes in this edition include the addition of a section on diseases of bones and joints and a discussion of the pertinent factors in diffuse collagen diseases, congenital hemolytic disease and some newer aspects in the field of hematology. Some chapters, as diseases of the liver, heart disease and pulmonary diseases, have been rewritten in whole or in part, to bring the information up to date.

Emphasis is placed in this book on the correlation of the physiological alterations leading to pathological changes and the relation of these changes to the mechanism of symptoms. To comprehend better these clinical changes, emphasis on the mechanics of organ alterations is important. This has value from the standpoint of the patient and the quest for a diagnosis and treatment of disease and from the standpoint of teaching either students or physicians. Other subjects, as Loeffler's pneumonia, lupus erythematosus cells, myeloid metaplasia and cortisone in rheumatoid arthritis enhance the value of this book.

Diseases involving various organs are arranged in different chapters, and the discussion includes the essential clinical features, prognosis, and pathology, which is reviewed in some detail, with a discussion on the relation of symptoms to lesions. The book is profusely illustrated with examples of the important pathological processes discussed, and the type and format are good. Dr. Boyd's studies in the field of pathology are known to the medical profession, and this most recent edition of his book is a valuable contribution to the field of medicine and pathology that should be in the possession of students and practicing physicians.

Food Poisoning: Its Nature, History and Causation; Measures for Its Prevention and Control. By Elliot B. Dewberry, M.B.E. Foreword by Gerald R. Leighton, O.B.E., M.D., D.Sc. In three parts with appendixes. Third edition. Cloth. 17s.6d. Pp. 318, with 64 illustrations. Leonard Hill Limited, 17 Stratford Place, London, W.1, 1950.

The book is loosely organized. Much of the difficulty is a result of using the term "bacterial food poisoning" both in its general sense and as a synonym for Salmonella food poisoning. A consideration of the various types of bacterial food poisoning occupies three quarters of the book. The remainder is devoted to poisonous metallic salts, poisonous plants, edible and poisonous fungi, poisonous fish and shellfish and food allergy. The final chapter gives brief directions for culturing and identifying the bacteria responsible for food poisoning. Throughout the book there is extensive direct quotation from the original literature, but recent advances are sometimes missing. In the chapter on poisonous metallic salts, no mention is made of cadmium, and phenothiazine is listed as a promising substitute for arsenical insecticides, without reference to any of the numerous more successful compounds developed later. It seems unlikely that the book will find much use in this country.

A German-English Dictionary for Chemists. By Austin M. Patterson. Third edition. Cloth. $5. Pp. 541. John Wiley & Sons, Inc., 440 4th Ave., New York 16, 1950.

During the 15 years since the publication of the last edition of this indispensable tool, tremendous technological advances have occurred. These changes are reflected in extensive additions to scientific terminology. In contrast to the 1935 edition's 42,000 entries, the 1950 edition is stated to embrace some 59,000 German terms of interest to chemists and chemical engineers. The terms are drawn from the literature of chemistry, physics, biology, geology, chemical technology, electronics, pharmacy and warfare. Like the earlier edition, this one has three especially interesting features: obsolete and antiquated chemical terms (so marked) occurring in the older chemical literature and often in current pharmaceutical writing, common general words which the user otherwise would have to look up in standard dictionaries and an introduction pointing out the principles of German chemical nomenclature.

Personality: A Systematic Theoretical and Factual Study. By Raymond B. Cattell, Research Professor, University of Illinois, Urbana. Cloth. $5.50. Pp. 689, with 54 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 18; Aldwych House, Aldwych, London, W.C.2, 1950.

This volume presents a discussion of recent theoretical and factual material concerning description and measurement of personality. Interaction of heredity and environment are described, and an attempt is made through synthesis of knowledge of clinical and experimental psychology to explain the dynamic processes of adjustment and learning. Special emphasis is placed on tying in sociologic and anthropological data for presentation of the study of personality on a more objective basis. Of particular interest are the last three chapters, in which the author considers the impact of all psychic factors in the process of development that contribute to life stages; of personality from conception through adolescence, maturity and old age. The volume is primarily designed for teaching purposes, and the author offers suggestions for scholastic use of the book on several graded levels.

The Breast: Structure, Function, Disease. Edited by F. D. Saner, M.B., B.Ch., F.R.C.S., Surgeon, Royal Northern Hospital, London. Cloth. $8.50. Pp. 316, with 193 illustrations. The Williams and Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1950.

In the preparation of this book, 15 persons collaborated. Their object was to present a general picture of the structure, function and disease of the breast and to include suggestions for treatment. The subjects covered are as follows: The structure of the breast, the function of the breast, abnormalities of structure and function, examination and diagnosis, mammary dysplasia: chronic mastitis, benign tumors, chronic infective lesions, the nipple and the skin, cancer: general considerations, invasion of the internal mammary lymphatic chain, treatment, radiotherapy, the plastic contribution to breast surgery, appendix (statistical data on breast cancer).

The authors of this book are to be congratulated on having compiled so much valuable data in such a small book. In spite of the fact that there were so many collaborators, the book is written in a smooth style; the illustrations are numerous; clear and instructive, and many are in color. Numerous American authorities are quoted throughout the book. At the end of each chapter is a well selected bibliography. The paper is sturdy, and the binding is good. The book is highly recommended to all physicians.

Nutrition & Diet Therapy. By Fairfax T. Proudfit, Director of Dietary Department, John Gaston Hospital, Memphis, Tenn., and Corinne Hogden Robinson, Lecturer in Nutrition and Dietetics, Temple University School of Medicine, Philadelphia. Tenth edition. Cloth. $4. Pp. 950, with 69 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1950.

The fact that this book has had so many editions is proof of its great usefulness as a textbook for students in nursing. It also, however, continues to be a helpful reference book for physicians and others who are concerned with the feeding of the sick. Recognition by the medical profession of the importance of diet therapy has increased greatly in the last few years. This is mainly because of the rapid progress being made in the science of nutrition and its practical application. The authors have brought the subject up to date in a brief, concise, well organized and well written text, documented satisfactorily and accompanied by excellently arranged tables giving data on food values, including those for sodium and potassium and for cholesterol, which has recently attracted much attention. Particularly helpful are the sections devoted to the newer knowledge in the field of proteins and amino acids, to mineral metabolism and to the vitamins. The authors are well qualified for this task, and their book can be highly recommended. Every general practitioner, every surgeon and others in the medical profession ought to have available for ready reference a volume such as this.

Surgery of the Eye: Injuries. By Alston Callahan, B.A., M.S., M.D., Professor of Ophthalmology, Medical College of Alabama, Birmingham. Cloth. $11.50. Pp. 217, with 333 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1950.

This book deals with the principles of treatment of injuries of the eye in a thorough and authoritative manner. The author formerly had wide experience with traumatic surgery of the eye as chief of the eye section of the Northington General Hospital in Tuscaloosa, Ala. The book is well written, beautifully illustrated and is a valuable reference.

QUERIES AND MINOR NOTES

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

BUBBLES IN CHRISTMAS TREE LIGHTS

To the Editor:—What is the nature of the solution in the Christmas tree lights that produce bubbles when lit? I had 2 small patients who broke the bulbs and either attempted to or did drink the contents. Gastric lavage was performed on both of them as a precaution and ill effects were not noted, but for future reference I would like to know whether or not the liquid is poisonous. J. S. Desporte, M.D., Bogalusa, La.

Answer.—Somewhat the same fluid that appears in the bubble type of Christmas tree lights may be found in certain advertising signs and in the birdlike novelty, the head of which automatically moves up and down. In the lights the fluid may be ethyl ether or methyl chloride, but other closely related chemicals can be used. In the novelty birds methyl chloride is almost certain to be found.

Evaporation of methyl chloride is likely to be so rapid that the fluid would largely disappear before imbibition. Methyl chloride, chiefly as a vapor, is decidedly toxic and has caused deaths when it leaked from refrigerator systems. In the manufacture of novelties exposed workers are known to have been injured. Ethyl ether is less toxic, and the degree of prospective damage is reflected in its wide use as an anesthetic. The properties of only a few chemicals lend themselves to the use under discussion, but methylene chloride, if it can be substituted, should be given preference since it involves neither major fire nor toxic damage.

UNDERDEVELOPED BREASTS

To the Editor:—A woman aged 35, has underdeveloped breasts. She says that her friends get injections that develop theirs. This woman is normal. Her menses are normal except for dysmenorrhea. M.D., New York.

Answer.—It is probable that underdeveloped breasts in an adult woman with normal and regular menses are due to an end organ defect rather than a deficiency of estrogenic hormone. However, this patient could be treated with estrogens, parenterally, orally or topically (inunction of estrogen in an oily or ointment base over the mammary region). There is little advantage in this latter method. The dosage should be comparable to that administered to women for the menopause syndrome. There is the possibility of interruption of the regularity of the menstrual cycle. This tendency would be minimized by administration of the estrogen beginning on the third day of menstruation and interruption about one week before the expected onset of the next cycle. If results are not distinctly encouraging after three months of such treatment, it is not worth continuing indefinitely.

CARBON MONOXIDE POISONING

To the Editor:—How long does the methemoglobin persist in the blood in carbon monoxide poisoning, and is this influenced by the patient's being in an oxygen tent for some time?

G. L. Lester, M.D., Chautauqua, N. Y.

Answer.—Carbon monoxide poisoning does not produce methemoglobin. This compound is oxidized hemoglobin—not to be confused with oxygenated hemoglobin—and is a physically stable substance most often encountered in toxicity due to such drugs as nitrites, aniline, acetanilide, antipyrine and methylene blue. Carbon monoxide combines with hemoglobin in the same unstable manner as oxygen, producing carboxyhemoglobin; its toxicity is dependent on the ability to compete with oxygen for the available hemoglobin. Since the affinity of hemoglobin for carbon monoxide is 200 to 300 times greater than for oxygen, relatively large amounts of carboxyhemoglobin may be found rapidly, although the alveolar concentration of carbon monoxide is small. The rate of removal of carbon monoxide depends, therefore, on the blood concentration when treatment is begun and on the rate and concentration of oxygen inhaled; usually it is removed in a matter of hours. Oxygen therapy, of course, increases the rate of this exchange.

WITHDRAWAL SYMPTOMS IN DRUG ADDICTION

To the Editor:—I have a patient, a narcotic addict, to whom it has been necessary to give rather large amounts of dihydromorphinone hydrochloride for about six months. Pain from Buerger's disease necessitated the use of the drug. I feel that the response I have obtained with various drugs used in the treatment of peripheral vascular disease has been such that my patient should not require much, if any, for pain. In my opinion there is no psychic factor, as the patient does not know the drug he has been given. Yet withdrawal symptoms appear when the drug is withdrawn. Are there any drugs of recent development or any recently developed methods that will help in withdrawal in this case?

Edwin E. Lyda, M.D., San Bernardino, Calif.

Answer.—The use of the term "treatment" is interpreted as treatment of physical dependence. There is no qualitative difference between physical dependence and withdrawal manifestations with dihydromorphinone and those observed with any other opiate. Parenthetically, since all the dangerous opiates are vasoconstrictors, it might be advisable in treating peripheral vascular disease to use a drug that has vasodilator action, e. g., meperidine hydrochloride. Since the introduction of methadone hydrochloride, withdrawal of narcotic drugs has been greatly simplified. Methadone is substituted for the narcotic being used, the proportion being 1 mg. of methadone hydrochloride to 4 mg. of morphine sulfate. Since methadone hydrochloride acts somewhat more slowly than does an opiate alkaloid, some overlap may be necessary, with an occasional "booster" dose of dihydromorphinone or morphine sulfate until the transfer is complete and the patient is physically dependent solely on methadone. After this point is reached, methadone therapy can be discontinued rather rapidly. In the laboratory, complete and sudden discontinuance results in a mild abstinence syndrome. In private practice, seven to 10 days should be ample.

There is always some risk in any withdrawal, and the physician should be willing and available to give an injection of some rapidly acting opiate if serious signs develop. These are vomiting, dilatation of the pupils and a steady rise in temperature. (As long as the pupils are decidedly contracted, one can feel fairly safe.) As was recognized in the query, this has nothing to do with emotional factors preceding or resulting from the administration of an opiate. Often a patient is receiving all the drug he needs but wants more. Here one must depend on signs, not symptoms. It is well to assume that a rise in temperature is an early manifestation of abstinence, not emotional or "faked." It is better to allow oneself to be deceived occasionally rather than have a fatality. Fatalities can occur with remarkable suddenness, if the physician is not willing to admit that some of the signs mentioned are those of abstinence. One warning is necessary: If the patient has also hypertensive cardiovascular disease, complete abstinence probably cannot be obtained. At about the equivalent of ⅛ grain (8 mg.) of morphine sulfate every four hours, or even higher, serious signs of abstinence appear. If the withdrawal is persisted in, decompensation and death are highly probable. The only recourse is a quick-acting opiate, or its equivalent, given promptly.

TREATMENT OF PARKINSONISM

To the Editor:—Is vitamin B_{12} of any value in Parkinson's disease (idiopathic type)? What is the present status of mephenesin (tolserol®) for this condition? If it is used, what dosages are recommended and how long may it be continued? Is crude liver of any value? M.D., Wisconsin.

Answer.—Parkinson's disease should be treated with a combination of (1) medicinal preparations, (2) physical therapy and (3) psychotherapy. The use of each of these will depend on the stage of the disease and the ability of the practitioner. Since parkinsonism is a chronic degenerative disease of the nervous system which usually extends over many years, the patient should be encouraged to maintain some form of activity as long as possible, without undue fatigue. These patients do much better if they are able to lead a relatively quiet existence, avoiding situations causing excessive emotional excitement. The nature of the illness should be carefully explained to each patient, with emphasis on its chronic nature and the fact that the disease does not ordinarily affect mental capability. Every effort should be made to avoid the use of alarming statements.

The prescription of one or more of the various antispasmodics is an individual matter, and satisfactory results are frequently obtained only after a period of trial. At the present time trihexyphenidyl would appear to give satisfactory results to the majority of patients with parkinsonism, without causing intolerable side reactions in any but a small number. The belladonna alkaloids, including hyoscine, stramonium and atropine, alone or in combination, also give satisfactory results in many cases. Physical therapy is a useful adjuvant where muscle soreness, pain, cramp or rigidity is prominent; relief often occurs with the use of heat and massage. Graded exercises also are helpful. Vitamin B_{12} and liver are of no value in parkinsonism. The benefit attributed to the use of mephenesin when this drug was first introduced has not been observed in more extensive studies.

RHEUMATOID ARTHRITIS

To the Editor:—A woman, aged 33, has had rheumatoid arthritis for 10 years. In 1948 she had a hysterectomy; at that time diabetes mellitus was discovered. The diabetes appears to be well controlled with 10 units of protamine zinc insulin and 13 units of regular insulin, although the patient has recently lost 12 pounds (5.4 Kg.). An attempt at treatment of the rheumatoid arthritis was made 10 years ago with a course of vaccines (details unknown). She now shows the typical deformities of the hand joints, one shoulder and one knee, with muscular atrophy. She is greatly handicapped for daily activities and walks with a limp. She weighs 90 pounds (41 Kg.) and is 5 feet 4 inches (163 cm.) tall. Clinically there does not seem to be any activity in the affected joints. The blood sedimentation rate is not yet known. The rheumatoid process has been slowly progressive. Is chrysotherapy any more hazardous in a diabetic than in a normal person? Pituitary adrenocorticotropic hormone (ACTH) is not available to me. Would desoxycorticosterone and intravenous administration of vitamin C be preferable to gold injections? The patient will be hospitalized throughout the period of treatment.

E. G. Wermuth, M.D., London, Ontario, Canada.

ANSWER.—Well controlled diabetes does not constitute a contraindication to gold therapy. If toxic manifestations ensue, then the presence of diabetes may make their handling more difficult and thus increase somewhat the total risk. Recent experience with the use of desoxycorticosterone acetate and vitamin C in the therapy of rheumatoid arthritis has failed to establish the value of this method of treatment. It, therefore, cannot be recommended, although, if tried, no adverse effect on the diabetes would be expected. Of the two methods, chrysotherapy would seem preferable, in a dosage not to exceed 50 mg. weekly of gold sodium thiomalate. A total of 1 Gm. should be given, followed, in case of improvement, by maintenance injections of 50 mg. every three to four weeks. In any case, general treatment, in the form of increased rest, acetylsalicylic acid to the point of relief of pain and stiffness and physical therapy, especially heat and active exercises, should not be neglected.

BIRTH CONTROL AND CHRONIC CYSTIC MASTITIS

To the Editor:—A patient of 27 years of age has chronic cystic mastitis of both breasts, more severe on the right side. Is she risking future neoplastic involvement of the cervix by using a diaphragm pessary?

Joseph Burns, M.D., Miami Beach, Fla.

ANSWER.—The use of a diaphragm pessary would indirectly influence the chronic cystic mastitis from which your patient suffers. This would come about from the continued ovarian stimulation to the breast without pregnancy intervening to permit normal physiological function. Carcinoma of the breast is more frequent in women who have had children but did not suckle them and married women who have prevented pregnancy. Inasmuch as the chronic cystic mastitis is evidence of endocrine dysfunction in this patient, the use of any instrument which might act as an irritant would be dangerous, because chronic irritation in a patient predisposed to malignant disease may hasten the neoplastic changes.

PHENOLSULFONPHTHALEIN SODIUM TEST

To the Editor:—Will the addition of an excess amount of sodium hydroxide have any adverse effect in the phenolsulfonphthalein sodium test of renal function? The more alkali added, the greater the precipitate in the urine. Does this precipitate carry down any pigment with it? I perform the test with the Dunning colorimeter.

M.D., Pennsylvania.

ANSWER.—Any reasonable excess of alkali likely to be used to develop the purple color will not produce an error in the test, as phenolsulfonphthalein is highly soluble in dilute sodium hydroxide.

NEVUS FLAMMEUS

To the Editor:—Is there any therapy—other than with solid carbon dioxide, electrodesiccation or a Kromayer lamp—available now for nevus flammeus? Radium cannot be used.

M.D., Massachusetts.

ANSWER.—None of the three methods mentioned is recommended for the treatment of nevus flammeus. Such destructive measures usually leave a mottled appearance which still constitutes a cosmetic defect. Grenz rays are said to produce satisfactory improvement, particularly when they are used in infancy, but experience with grenz rays has not been extensive. The introduction of pigment into the nevus by tattoo has been recommended by Conway and Doktor (*Surg., Gynec. & Obst.* 84:866 [April] 1947), but experience with this method has been limited.

HYPOGONADISM

To the Editor:—I would appreciate any suggestions or course of treatment for hypogenitalism in a 28 year old patient.

M.D., New York.

ANSWER.—The type of treatment depends on the type of hypogonadism. If it is primary and the result of some defect in the testes or associated with bilateral undescended testes, androgen therapy should be employed, with testosterone propionate in a dose of 25.0 mg. three times a week by intramuscular injection. If it is secondary to hypopituitarism, chorionic gonadotropin should be administered in a dose of 500.0 I. U. three times a week by intramuscular injection. If any other glandular deficiency is present in addition to hypogonadism, such as hypothyroidism, it should be corrected by appropriate therapy.

LOW DIASTOLIC PRESSURE IN YOUNG PATIENTS

To the Editor:—The reply to the two queries relative to "zero" diastolic blood pressure in normal persons (*J. A. M. A.* **144**:512 [Oct. 7] 1950) warrants further elaboration. The syndrome as initially described by me (Transient "O" Diastolic Brachial Pressure [Indirect], Associated with Normal or Elevated Popliteal Pressure, Tachycardia and Nervous Tension, *Am. Heart J.* **30**:381 [Oct.] 1945) consisted of several principal components: (1) a brachial diastolic pressure recorded as O by the indirect method, i. e., by the ordinary sphygmomanometer, (2) its transient character (five minutes to 1½ hours in the cases described), (3) a normal or elevated blood pressure in the lower extremities, (4) tachycardia and (5) nervous tension. Thirty-five of the 38 patients described were between the ages of 18 and 30 years, with the major age distribution below 25.

The syndrome is benign. While the exact mechanisms involved in its genesis are not clear, existing evidence would suggest the operation of intense psychoneurogenic influences and consequent transitory autonomic nervous system imbalance producing rather pronounced vasodilatation in the muscle bed of the upper extremities (and probably other regions) and initiating certain compensatory reflex mechanisms that maintain normal vascular tone or bring about vasoconstriction in the lower extremities to assure adequate cerebral flow. It has been demonstrated experimentally that the lower extremities are more responsive to vasoconstrictor influences than are the upper extremities. These are discussed in more detail in the original paper.

Clinically, the syndrome, unless borne in mind, may create considerable diagnostic confusion and may lead to an erroneous impression of organic aortic insufficiency. However, if the ordinary criteria of the latter are fulfilled, there should be little difficulty in making the distinction. The absence of a history of rheumatic fever or syphilis, together with the failure to elicit a diastolic murmur, absence of cardiac enlargement, the transitory nature of the "O" diastolic reading in the upper extremities and the presence of normal or elevated blood pressure (systolic and diastolic) in the lower extremities ordinarily differentiate this benign phenomenon from aortic insufficiency.

Functional aortic insufficiency presents no problem in differential diagnosis since dynamically it is rarely of sufficient magnitude to produce a diastolic pressure of less than 60 mm. of mercury (Garvin, C. F.: Functional Aortic Insufficiency, *Ann. Int. Med.* **13**:1799, 1940). It is needless to point out, of course, that reasonable care should be exercised to exclude a false low reading associated with excessive pressure on the antecubital space with the stethoscope piece. However, this pitfall is more theoretical than real. In actual practice a zero diastolic reading due to pressure-induced artefact would require far more force than is ordinarily applied clinically; it would necessitate a deliberately strong pressure.

There would appear to be little doubt that the syndrome is considerably more common than is generally appreciated. Further, while it has not as yet been reported in children, it probably is not rare in this group.

INJECTION OF WHOLE BLOOD INTO INFANTS

To the Editor:—In reply to the query in *The Journal*, Sept. 30, 1950, page 437, concerning injections of whole blood into infants, no mention is made of the possibility of transmission of serum jaundice (hepatitis). This is a serious disease in infants, and, therefore, blood should not be given intramuscularly unless overwhelming evidence is present that it would be of benefit.

Jack Troy, M.D., Whiting, Ind.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, SEPTEMBER-DECEMBER 1950

Titles have been listed or abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past four months Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in Continental United States and Canada and to members of the American Medical Association for a period not exceeding five days. Three journals may be borrowed at a time. No journals are available prior to 1939. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in The Journal. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "OS," Organization Section; "ab," abstracts; the asterisk (*) indicates an original article in The Journal.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For the author index see page 1661.

A

ACS: See Bogomolets Antireticular Cytotoxic Serum
ACTH
  action, mode of, [Heilmeyer] 1591—ab
  carbohydrate metabolism and [Overbeck] 1522—ab
  Conference (second) 1274
  course on use, (W. Va.) 325; (Jefferson Medical College) 771; (Wis.) 1492
  effect on reproduction, [Tompkins] 261—C
  effect on wound healing, 47—E
  eosinophil count response to, after giving cortisone, [Sprague & others] *1341
  eosinophilia, Thorn test in, [Hernandez Morales & others] *379
  Nobel Prize for 1950 awarded to Drs. Hench, Kendall and Reichstein, 819—E
  physiological effects in man, [Sprague & others] *1341
  research, millions for, approved by Truman, 696
  screening test for, ephedrine in, [Abelson] 716—ab
  supply, [Hench & others] *1331
  supply, for U. S. Army hospitals in Korea, etc., 471
  symposium on, at A.M.A. Section, [Hench & others] *1327; [Massell & Warren] *1335; [Sprague & others] *1341; [Howard & others] *1347; [Pearson & Eliel] *1319; [Shy & others] *1353
  symposium on, at International Congress of Pediatrics, Switzerland, 777
  toxicity, [Hench & others] *1328
  toxicity: Cushing's syndrome [Taylor & others] *1063
  toxicity: fatty infiltration of liver, [Pelner & Waldman] 412—C
  toxicity: hypercholesteremia, [Adlersberg & others] *909
  toxicity: perforated duodenal ulcer, [Habif & others] *996
  toxicity: skin complications, [Behrman & Goodman] *218
  Treatment: See also Allergy; Arthritis, Rheumatoid; Cancer; Cushing's Syndrome; Eyes, diseases; Glaucoma; Gout; Hodgkin's Disease; Keratitis; Kidneys, disease; Leukemia; Lupus erythematosus; Lymphoma; Peptic Ulcer; Purpura; Reiter's Disease; Rheumatic Fever; Uveitis
  treatment of malignant conditions, [Spies] 1036—ab
  treatment, prolonged, lipemic variations after, Italy, 1107; 1393
ABDOMEN: See also Ascites; Gastrointestinal Tract; Pelvis
  acute conditions, and alcoholism, 1213—ab
  acute conditions, hemophilia simulating, [Shelton] 1212—ab
  Adhesions: See Adhesions
  hemorrhage due to rupture of uterine vessel by twisted fibroid, [Kaye & Ficarra] *616
  Surgery: See also Cesarean Section; Gallbladder
  surgery, automatic *electroencephalographically* controlled anesthesia in, [Mayo & others] *1081
  Viscera: See Viscera
  wall flaps for grafting ileostomy or colostomy stoma, [Pickrell] 423—ab
ABELL, IRVIN, memorial clock at Louisville, 698
ABNORMALITIES: *See under specific organ* and region as Heart; Kidneys
ABORTION
  Conference on Pregnancy Wastage, 1579
  habitual, 80
  preconception clinic established, New York, 1273
  therapeutic, in rubella, Sao Paulo, Brazil, 779
  vaginal smear in, [Benson] 955—ab
ABSCESS: See Ulcers, under organs affected as Brain; Teeth; Tonsils
  Psoas: See Muscles, psoas
ABSORPTION: See Insulin; Intestines; Vitamins
ABT Lecture: See Lectures
ACACIA
  allergy to pharmaceutical excipients, [Randolph] 1027—ab
ACADEMY: See also under names of specific academies as American Academy; Kalamazoo Academy; National Academy; New York Academy; list of Societies at end of letter S
  of Sciences of Ferrara discusses androgens therapy, 481
ACCELERATION: See Aviation
ACCIDENTS: See also Disasters; Trauma; Wounds
  Accident Handbook, for use in home published by Children's Hospital of Boston, 1007—E
  Automobile: See Automobiles
  fatal home, decline, 57
  in children, American Academy of Pediatrics Committee to reduce, 192; 1015; 1183—E
  in children: deaths; crippling, [Dietrich] *1175; 1183—E
  Industrial: See Industrial Accidents
  Insurance: See Insurance
  prevention, Council report, 649
ACETARSONE
  efficacy in congenital syphilis, [Nyhus] 1037—ab
ACETRIZOATE, sodium, N.N.R. (description) 623; (Mallinckrodt) 623
ACETYLAMINOFLUORENE
  thyroid tumor produced with, [Doniach] 1519—ab
ACID
  Amino Acids: See Amino Acids
  aminoacetic, glycine and calcium carbonate, N.N.R., (Schenley), 314
  p-aminobenzoic, treatment of typhus, [Chung] 798—ab
  p-aminosalicylic and its calcium salt, treatment of typhoid and brucellosis, 1498
  p-aminosalicylic, derivative in genitourinary tuberculosis, [Debray] 801—ab
  p-aminosalicylic (lupulon) treatment of leprosy, [Johansen & Erickson] *989
  p-aminosalicylic, N.N.R. (description) 760; (Merck) 760
  p-aminosalicylic plus streptomycin in renal tuberculosis, 809
  p-aminosalicylic, plus streptomycin, in tuberculous meningitis, [Rossi] 274—ab
  p-aminosalicylic, reactions to, Paris, 255
  p-aminosalicylic, synergism and antagonism, [Bigger] 716—ab
  p-aminosalicylic, treatment of chronic pulmonary tuberculosis, [Dooneief] 344—ab
  p-aminosalicylic, treatment of tuberculosis, [Heilmeyer] 428—ab
  amylethyl barbituric, treatment of depressed patient, [Grahn] 1303—ab
  Ascorbic: See also Vitamins C
  ascorbic, and desoxycorticosterone in rheumatoid arthritis, 1107; [Graham] 1121—ab
  ascorbic, excretion, and hypoxia, [Krasno] 1404—ab
  ascorbic, in adipose tissue, [Page] 1590—ab
  ascorbic, plus deoxycortone in rheumatoid arthritis, [Bywaters] 271—ab
  ascorbic, treatment of arthropathies, [Buttaro] 502—ab
  ascorbic, treatment of whooping cough, [DeWit] 879—ab
  boric, synergism and antagonism, [Bigger] 716—ab
  Cevitamic: See Acid, ascorbic
  folic, and vitamin B_{12} in pernicious anemia, [Schrumpf] 1039—ab
  Folic, Antagonist: See Aminopterin; Amethopterin
  folic, in pernicious anemia and related megaloblastic anemia, [Vilter] 954—ab
ACID—Continued
  folic, treatment of anemias, [Haehner] 962—ab
  folic, treatment of pernicious anemia, long term evaluation, [Schwartz] 419—ab
  glutamic, treatment of petit mal epilepsy, 724
  iodoacetic, irritant action of in biochemist, [Flesch] 1110—C
  nicotinic, deficiencies, [Youmans] *386
  Nicotinic, Diethylamide of: See Nikethamide
  pyruvic, level in blood, carbohydrate metabolism disturbed in diabetes, 1394
  salicylic therapy, possibilities of solusal, [Blumencron] 1216—ab
  undecylenic, exfoliative dermatitis after its use in psoriasis, [Schiff] *620
  undecylenic, N.F., N.N.R. (description) 761; (Wallace & Tiernan) 761
  undecylenic, sevinon treatment of leprosy, [Johansen & Erickson] *989
ACID-BASE BALANCE
  disturbances, water-chloride balance in, [Scribner & others] *1171
ACIDITY
  Gastric: See Stomach acidity
ACIDOSIS
  Diabetic: See Diabetes Mellitus
ACNE
  treatment, pigmentation after, 1419
ACRYLIC prosthesis, 197
ACTINOMYCES, Antibiotic Prepared from: See Streptomycin
ACTINOMYCOSIS
  treatment, aureomycin hydrochloride, [Wright & Lowen] *21
ACTIVITY: See Exercise
  following Operation or Illness: See Convalescence
ACUPUNCTURE
  treatment of keloids, 858
ADAIR Foundation: See Foundations
ADAPTATION: See Eyes, accommodation
ADDICTION: See Alcoholism; Drugs; Narcotics
ADDISON'S ANEMIA: See Anemia, Pernicious
ADDISON'S DISEASE
  pathogenesis, [O'Donnell] 871—ab
  treatment, streptomycin, [Guy-Laroche] 1523—ab
  without increased pigmentation, [Hedinger] 430—ab
ADDRESSES: See Lectures
  at A.M.A. Session: See American Medical Association, Section on . . ., chairman's address
ADENITIS See Lymphatic System
ADENOCARCINOMA
  of uterus, diagnosis by genital smears, [Cuyler] 1516—ab
  papillary, of ovary, 697
  papillary, of thyroid; radioactive iodine for metastases to lung, [Freedberg & others] *16
ADENOMA
  Nontoxic, of Thyroid: See Goiter
  parathyroid, and renal calculi, [Kretschmer] 420—ab
  pituitary, degenerative changes in, [Brougham] 1306—ab
  pituitary, radiotherapy, [Buschke] 497—ab
  Toxic, of Thyroid: See Goiter, Toxic
ADENOMYOSIS: See Endometriosis
ADHESIONS
  peritoneal, plication for, [Ripstein] 954—ab
ADOLESCENCE
  erythrocyte values of adolescent workers, Brazil, 1500
  Midcentury White House Conference on, 1996—E; 1380; 1467—E
  precocious puberty, adrenal cortex tumor in boy of 6, [Lynch] *921
ADRENALECTOMY See Adrenals
ADRENALINE: See Epinephrine
ADRENALS See also Addison's Disease
  Adrenocorticotropic Hormone: See ACTH

ADRENALS—Continued
  adrenocorticotropics, personality classification, 1536
  cortex activity, Thorn test of eosinophilia, [Hernandez Morales & others] *379
  cortex and homeostasis, 1006—E
  cortex atrophy after ACTH and cortisone, [Sprague & others] *1346
  Cortex Compound L. See Cortisone
  cortex, excretion of steroids as an aid in diagnosis, 464—ab
  cortex extract (aqueous) dosage vs insulin requirement, [Green & others] *442
  cortex extract, treatment plus tostosterone for asthenia, France, 859
  cortex extracts, effect, [Hench & others] *1332
  cortex function and postoperative retention of salt and water, [Hardy] 1403—ab
  cortex function and postoperative salt retention, [Johnson] 1511—ab
  cortex, functional tumor in male child aged 6, [Lynch] *921
  Cortex Hormone (Crystalline): See Desoxycorticosterone
  cortex hyperglycemia, [Wilder] *1237
  cortex response to stress, role of potassium, [Hoagland] 495—ab
  excision, bilateral adrenalectomy in malignant hypertension and diabetes, [Green & others] *439
  Hormone (Sympathetic): See Epinephrine
  hyperplasia, cause of large genitals in infant, 725
  insufficiency in infancy, [Geppert] 713—ab
  tumors, pheochromocytoma, 396—E; [Bartels] 488—ab; [Koffler] 1028—ab
  tumors, pheochromocytoma, increased urinary arterenol and epinephrine, [Engel] 1408—ab
  tumors, piperoxan (benodaine) aids in removal, [Kositchek & Rabwin] *826
  weight after giving cortisone, [Sprague & others] *1345
ADRENOCORTICOTROPIC HORMONE: See ACTH
ADVERTISING
  Campaign of A M A: See American Medical Association, National Education Program
  emblem for advertising accepted in Today's Health, 635
  medical, [Boles] *364
  newspaper, of CIO National Health Committee, 933—E
